Dedication

With love for my guys,

Sam, Zach, and Max
Praise for Mark Sobell's Books

"I keep searching for books that collect everything you want to know about a subject in one place, and keep getting disappointed. Usually the books leave out some important topic, while others go too deep in some areas and must skim lightly over the others. A Practical Guide to Red Hat® Linux® is one of those rare books that actually pulls it off. Mark G. Sobell has created a single reference for Red Hat Linux that cannot be beat! This marvelous text (with a 4-CD set of Linux Fedora Core 2 included) is well worth the price. This is as close to an "everything you ever needed to know" book that I've seen. It's just that good and rates 5 out of 5."

─Ray Lodato Slashdot contributor

"Mark Sobell has written a book as approachable as it is authoritative."

─Jeffrey Bianchine Advocate, Author, Journalist

"Excellent reference book, well suited for the sysadmin of a linux cluster, or the owner of a PC contemplating installing a recent stable linux. Don't be put off by the daunting heft of the book. Sobell has striven to be as inclusive as possible, in trying to anticipate your system administration needs."

─Wes Boudville Inventor

"A Practical Guide to Red Hat® Linux® is a brilliant book. Thank you Mark Sobell."

─C. Pozrikidis University of California at San Diego

"This book presents the best overview of the Linux operating system that I have found. . . . [It] should be very helpful and understandable no matter what the reader's background is: traditional UNIX user, new Linux devotee, or even Windows user. Each topic is presented in a clear, complete fashion and very few assumptions are made about what the reader knows. . . . The book is extremely useful as a reference, as it contains a 70-page glossary of terms and is very well indexed. It is organized in such a way that the reader can focus on simple tasks without having to wade through more advanced topics until they are ready."

─Cam Marshall Marshall Information Service LLC Member of Front Range UNIX Users Group [FRUUG] Boulder, Colorado

"Conclusively, this is THE book to get if you are a new Linux user and you just got into RH/Fedora world. There's no other book that discusses so many different topics and in such depth."

─Eugenia Loli-Queru Editor in Chief OSNews.com
Preface

*A Practical Guide to Linux® Commands, Editors, and Shell Programming* explains how to work with the Linux operating system from the command line. The first few chapters quickly bring readers with little computer experience up to speed. The rest of the book is appropriate for more experienced computer users. This book does not describe a particular release or distribution of Linux but rather pertains to all recent versions of Linux.
Command line interface (CLI)

In the beginning there was the command line (textual) interface (CLI), which enabled you to give Linux commands from the command line. There was no mouse or icons to drag and drop. Some programs, such as *emacs*, implemented rudimentary windows using the very minimal graphics available in the ASCII character set. Reverse video helped separate areas of the screen. Linux was born and raised in this environment.

Naturally all of the original Linux tools were invoked from the command line. The real power of Linux still lies in this environment, which explains why many Linux professionals work *exclusively* from the command line. Using clear descriptions and lots of examples, this book shows you how to get the most out of your Linux system using the command line interface.
Linux distributions

A Linux distribution comprises the Linux kernel, utilities, and application programs. Many distributions are available, including Debian, Red Hat, Fedora Core, SUSE, Mandriva (formerly Mandrake), KNOPPIX, and Slackware. Although the distributions differ from one another in various ways, all of them rely on the Linux kernel, utilities, and applications. This book is based on the code that is common to most distributions. As a consequence you can use it regardless of which distribution you are running.
Overlap

If you read *A Practical Guide to Red Hat® Linux®: Fedora Core™ and Red Hat Enterprise Linux, Second Edition*, or a subsequent edition, you will notice some overlap between that book and the one you are reading now. The introduction, the appendix on regular expressions, and the chapters on the utilities (Chapter 3 of this book *not Part V*), the filesystem, and programming tools are very similar in the two books. The three chapters that cover the Bourne Again Shell (*bash*) have been expanded and rewritten for this text. Chapters that appear in this book and but not in *A Practical Guide to Red Hat® Linux®, Second Edition*, include those covering the *vim* and *emacs* editors, the TC Shell (*tcsh*), the *gawk* and *sed* languages, and Part V, which describes 80 of the most useful Linux utility programs in detail.
**Audience**

This book is designed for a wide range of readers. It does not require programming experience, although some experience using a general-purpose computer is helpful. It is appropriate for the following readers:

- **Students** taking a class in which they use Linux
- **Power users** who want to explore the power of Linux from the command line
- **Professionals** who use Linux at work
- **System administrators** who need a deeper understanding of Linux and the tools that are available to them
- **Computer science students** who are studying the Linux operating system
- **Programmers** who need to understand the Linux programming environment
- **Technical executives** who want to get a grounding in Linux
Benefits

A Practical Guide to Linux® Commands, Editors, and Shell Programming gives you an in-depth understanding of how to use Linux from the command line. Regardless of your background, it offers the knowledge you need to get on with your work: You will come away from this book understanding how to use Linux, and this text will remain a valuable reference for years to come.
Features Of This Book

This book is organized for ease of use in different situations. For example, you can read it from cover to cover to learn command line Linux from the ground up. Alternatively, once you are comfortable using Linux, you can use this book as a reference: Look up a topic of interest in the table of contents or index and read about it. Or, refer to one of the utilities covered in Part V, "Command Reference." You can also think of this book as a catalog of Linux topics: Flip through the pages until a topic catches your eye. The book also includes many pointers to Web sites where you can get additional information: Consider the Web an extension of this book.

A Practical Guide to Linux® Commands, Editors, and Shell Programming offers the following features:

- **Optional sections** allow you to read the book at different levels, returning to more difficult material when you are ready to tackle it.

- **Caution boxes** highlight procedures that can easily go wrong, giving you guidance before you run into trouble.

- **Tip boxes** highlight places in the text where you can save time by doing something differently or when it may be useful or just interesting to have additional information.

- **Security boxes** point out ways that you can make a system more secure.

- The Supporting Web site at www.sobell.com includes corrections to the book, downloadable examples from the book, pointers to useful Web sites, and answers to even-numbered exercises.

- Concepts are illustrated by practical examples found throughout the book.

- The many useful URLs (Internet addresses) identify sites where you can obtain software and information.

- **Chapter summaries** review the important points covered in each chapter.

- **Review exercises** are included at the end of each chapter for readers who want to hone their skills. Answers to even-numbered exercises are available at www.sobell.com.

- Important GNU tools, including gcc, gdb, GNU Configure and Build System, make, gzip, and many others, are described in detail.

- Pointers throughout the book provide help in obtaining online documentation from many sources, including the local system and the Internet.
This section describes the information that each chapter covers and explains how that information can help you take advantage of the power of Linux. You may want to review the table of contents for more detail.

- **Chapter 1 Welcome to Linux** Presents background information on Linux. This chapter covers the **history of Linux**, explains how the GNU Project helped Linux get started, and discusses some of Linux's **important features** that distinguish it from other operating systems.

**Part I: The Linux Operating System**

**tip**: Experienced users may want to skim **Part I**

If you have used a UNIX/Linux system before, you may want to skim or skip some or all of the chapters in **Part I**. All readers should take a look at "Conventions Used in This Book" (page 22), which explains the typographic conventions that this book uses, and "Getting the Facts: Where to Find Documentation" (page 29), which points you toward both local and remote sources of Linux documentation.

**Part I** introduces Linux and gets you started using it.

- **Chapter 2 Getting Started** Explains the **typographic conventions** that this book uses to make explanations clearer and easier to read. This chapter provides basic information and explains how to log in, **change your password**, give Linux commands using the shell, and **find system documentation**.

- **Chapter 3 Command Line Utilities** Explains the **command line interface** (CLI) and briefly introduces **more than 30 command line utilities**. Working through this chapter gives you a feel for Linux and introduces some of the tools you will use day in and day out. The utilities covered in this chapter include:

  - grep, which **searches through files** for strings of characters;
  - unix2dos, which **converts Linux text files** to Windows format;
  - tar, which **creates archive files** that can hold many other files;
  - bzip2 and gzip, which **compress files** so that they take up less space on disk and allow you to transfer them over a network more quickly; and
  - diff, which **displays the differences** between two text files.

- **Chapter 4 The Linux Filesystem** Discusses the Linux hierarchical filesystem, covering files, filenames, **pathnames**, working with directories, **access permissions**, and hard and **symbolic links**. Understanding the filesystem allows you to **organize your data** so that you can find information quickly. It also enables you to **share some of your files** with other users while **keeping other files private**.

- **Chapter 5 The Shell** Explains how to use shell features to make your work faster and easier. All of the features covered in this chapter work with both **bash** and **tcsh**. This chapter discusses:

  - Using **command line options** to modify the way a command works;
  - How a minor change in a command line can **redirect input** to a command to come from a file instead of the keyboard;
  - How to **redirect output** from a command to go to a file instead of the screen;
- Using **pipes** to send the output of one utility directly to another utility so that you can solve problems right on the command line;

- Running programs in the **background** so that you can work on one task while Linux is working on a different one; and

- Using the shell to **generate filenames** to save you time spent on typing and help you when you do not remember the exact name of a file.

**Part II: The Editors**

**Part II** covers two classic, powerful Linux command line text editors. Most Linux distributions include the **vim** text editor, an "improved" version of the widely used **vi** editor, as well as the popular GNU **emacs** editor. Text editors enable you to create and modify text files that can hold programs, shell scripts, memos, and input to text formatting programs. Because Linux system administration involves editing text-based configuration files, skilled Linux administrators are adept at using text editors.

- **Chapter 6 The vim Editor** Starts with a tutorial on **vim** and then explains how to use many of the advanced features of **vim**, including special characters in search strings, the General-Purpose and Named buffers, parameters, markers, and execution of commands from **vim**. The chapter concludes with a **summary of vim commands**.

- **Chapter 7 The emacs Editor** Opens with a tutorial and then explains many of the features of the **emacs** editor as well as how to use the META, ALT, and ESCAPE keys. The chapter also covers key bindings, buffers, and **incremental and complete searching** for both character strings and regular expressions. In addition, it details the relationship between Point, the cursor, Mark, and Region. It also explains how to take advantage of the extensive **online help** facilities available from **emacs**. Other topics covered include cutting and pasting, using multiple windows and frames, and working with **emacs** modes—specifically **C mode**, which aids programmers in writing and debugging C code. **Chapter 7** concludes with a **summary of emacs commands**.

**Part III: The Shells**

**Part III** goes into more detail about **bash** and introduces the TC Shell (**tcsh**).

- **Chapter 8 The Bourne Again Shell** Picks up where **Chapter 5** leaves off, covering more advanced aspects of working with a shell. For examples it uses the Bourne Again Shell (**bash**), the shell used almost exclusively for system shell scripts. **Chapter 8** describes how to

  - Use shell **startup files**, shell options, and shell features to **customize your shell**;

  - Use **job control** to stop jobs and move jobs from the foreground to the background and vice versa;

  - Modify and reexecute commands using the **shell history** list;

  - Create **aliases** to customize commands;

  - Work with **user-created and keyword variables** in shell scripts;

  - Set up **functions**, which are similar to shell scripts but can execute more quickly;

  - Write and execute simple **shell scripts**; and
Redirect error messages so that they go to a file instead of the screen.

- **Chapter 9 The TC Shell** Describes `tcsh` and covers features that are common to and different between `bash` and `tcsh`. This chapter explains how to
  - Run `tcsh` and change your default shell to `tcsh`;
  - Redirect error messages so that they go to files instead of the screen;
  - Use control structures to alter the flow of control within shell scripts;
  - Work with `tcsh` array and numeric variables; and
  - Use shell builtin commands.

### Part IV: Programming Tools

Part IV covers programming under Linux. It discusses the C programming environment, the use of `bash` as a programming language, and ways to write programs using `gawk` and `sed`.

- **Chapter 10 Programming Tools** Introduces Linux's exceptional programming environment. This chapter
  - Explains how to invoke the GNU `gcc` compiler;
  - Describes how to use `make` to keep a set of programs up-to-date;
  - Explains how to debug a C program using `gdb`;
  - Describes how to work with shared libraries;
  - Explains how to set up and use CVS to manage and track program modules in a software development project; and
  - Discusses system calls and explains how you can use them to initiate kernel operations.

Once you have mastered the basics of Linux, you can use your knowledge to build more complex and specialized programs, using the shell as a programming language.

- **Chapter 11 Programming the Bourne Again Shell** Shows how to use `bash` to write advanced shell scripts. This chapter discusses
  - Control structures such as if...then...else and case;
  - Variables, including locality of variables;
  - Arithmetic and logical (Boolean) expressions; and
  - Some of the most useful shell builtin commands, including `exec`, `trap`, and `getopts`.

Chapter 11 poses two complete shell programming problems and then shows you how to solve them step by step. The first problem uses recursion to create a hierarchy of directories. The second problem develops a quiz program and shows you how to set up a shell script that interacts with a user and how the script
processes data. (The examples in Part V also demonstrate many features of the utilities you can use in shell scripts.)

- **Chapter 12 The gawk Pattern Processing Language** Explains how to write programs using the powerful *gawk* language that filter data, write reports, and retrieve data from the Internet. The advanced programming section describes how to set up two-way communication with another program using a *coprocess* and how to obtain input over a network instead of from a local file.

- **Chapter 13 The sed Editor** Describes *sed*, the noninteractive stream editor that finds many applications as a filter within shell scripts. This chapter discusses how to use *sed*'s buffers to write simple yet powerful programs and includes many examples.

**Part V: Command Reference**

Linux includes hundreds of utilities. Chapters 11 and 12 as well as Part V provide extensive examples of the use of more than 80 of the **most important utilities** with which you can solve problems without resorting to programming in C. If you are already familiar with UNIX/Linux, this part of the book will be a valuable, **easy-to-use reference**. If you are not an experienced user, it will serve as a useful supplement while you are mastering the earlier sections of the book.

Although the descriptions of the utilities in Chapters 11 and 12 and Part V are presented in a format similar to that used by the Linux manual (man) pages, they are much easier to read and understand. These utilities were chosen because you will work with them **day in and day out** (for example, *ls* and *cp*), because they are **powerful tools** that are especially useful in shell scripts (*sort*, *paste*, and *test*), because they help you **work with your Linux system** (*ps*, *kill*, and *fsck*), or because they enable you to **communicate with other systems** (*ssh*, *scp*, and *ftp*). Each utility description includes complete explanations of its most useful options. The "Discussion" and "Notes" sections present **tips and tricks** for using the utility to full advantage. The "Examples" sections demonstrate how to use these utilities in real life, alone and together with other utilities to generate reports, summarize data, and extract information. Take a look at the "Examples" sections for **gawk** (more than 20 pages, starting on page 537), **ftp** (page 674), and **sort** (page 764) to see how extensive these sections are.

**Part VI: Appendixes**

Part VI includes the appendixes, the glossary, and the index.

- **Appendix A Regular Expressions** Explains how to use **regular expressions** to take advantage of the **hidden power of Linux**. Many utilities, including *grep*, *sed*, *vim*, and *gawk*, accept regular expressions in place of simple strings of characters. A single regular expression can match many simple strings.

- **Appendix B Help** Details the steps typically used to **solve the problems** you may encounter with a Linux system. This appendix also includes many **links to Web sites** that offer **documentation**, useful Linux information, mailing lists, and **software**.

- **Appendix C Keeping the System Up-to-date** Describes how to use tools to download software and **keep your system current**. This appendix includes information on
  
  - **yum** Downloads software from the Internet, keeping a system up-to-date and **resolving dependencies** as it goes.
  
  - **Apt** An alternative to **yum** for keeping a system current.
• **BitTorrent** Good for distributing large amounts of data such as Linux installation CDs.

• **Glossary** Defines more than 500 terms that pertain to the use of Linux.

• **Index** Helps you find the information you want quickly.
Supplements

The author's home page (www.sobell.com) contains downloadable listings of the longer programs from this book as well as pointers to many interesting and useful Linux-related sites on the World Wide Web, a list of corrections to the book, answers to even-numbered exercises, and a solicitation for corrections, comments, and suggestions.
Thanks

First and foremost I want to thank my editor at Prentice Hall PTR, Mark L. Taub, who encouraged me and kept me on track. Mark is unique in my experience: He is an editor who works with the tools I am writing about. Because Mark runs Linux on his home computer, we could share experiences as I wrote. His comments and direction were invaluable. Thank you, Mark T.

A big "Thank You" to the folks who read through the drafts of the book and made comments that caused me to refocus parts of the book where things were not clear or were left out altogether: Lars Kellogg-Stedman, Harvard University; Jim A. Lola, Principal Systems Consultant, Privateer Systems, LLC; Eric S. Raymond, cofounder, Open Source Initiative; Scott Mann; Randall Leichlitner, Independent Computer Consultant; Jason Wertz, Computer Science Instructor, Montgomery County Community College; Justin Howell, Solano Community College; Ed Sawicki, The Accelerated Learning Center; David Mercer, ConTechs; Jeffrey Bianchine, Advocate, Author, Journalist; John Kennedy; Chris Carr; and Jim Dennis, Starshine Technical Services.

Thanks to Molly Sharp of ContentWorks, the production manager who made sure the book came together as it was supposed to, and to Jill Hobbs, the copy editor who kept the various parts of the English language in their proper relative places. Thanks also to the folks at Prentice Hall PTR who helped bring this book to life: Heather Fox, Publicist; Suzette Ciancio, Marketing Manager; Robin O'Brien, Executive Marketing Manager; Julie Nahil, Full-Service Production Manager; Noreen Regina, Editorial Assistant; and everyone else who worked behind the scenes to make this book happen.

I am also indebted to Denis Howe, the editor of The Free On-Line Dictionary of Computing (FOLDOC). Dennis has graciously permitted me to use entries from his compilation. Be sure to visit the dictionary (www.foldoc.org).

Dr. Brian Kernighan and Rob Pike graciously allowed me to reprint the bundle script from their book, The UNIX Programming Environment (Prentice Hall, 1984).

Parts of A Practical Guide to Linux® Commands, Editors, and Shell Programming have grown from my previous Linux books and I want to thank the people who helped with those books.

Thank you to David Chisnall, computer scientist extraordinaire; Carsten Pfeiffer, Software Engineer and KDE Developer; Aaron Weber, Ximian; Matthew Miller, Boston University; Cristof Falk, Software Developer at CritterDesign; Scott Mann, IBM, Systems Management and Integration Professional; Steve Elgersma, Computer Science Department, Princeton University; Scott Dier, University of Minnesota; and Robert Haskins, Computer Net Works.

Thanks also to Dustin Puryear, Puryear Information Technology; Gabor Liptak, Independent Consultant; Bart Schaefer, Chief Technical Officer, iPost; Michael J. Jordan, Web Developer, Linux Online Inc.; Steven Gibson, owner of SuperAnt.com; John Viega, founder and Chief Scientist, Secure Software, Inc.; K. Rachael Treu, Internet Security Analyst, Global Crossing; Kara Pritchard, K & S Pritchard Enterprises, Inc.; Glen Wiley, Capitol One Finances; Karel Baloun, Senior Software Engineer, Looksmart, Ltd.; Matthew Whitworth; Dameon D. Welch-Abernathy, Nokia Systems; Josh Simon, Consultant; Stan Isaacs; and Dr. Eric H. Herrin II, Vice President, Herrin Software Development, Inc. And thanks to Doug Hughes, long-time system designer and administrator, who gave me a big hand with the sections on system administration, networks, the Internet, and programming.

More thanks go to consultants Lorraine Callahan and Steve Wampler; Ronald Hiller, Graburn Technology, Inc.; Charles A. Plater, Wayne State University; Bob Palowoda; Tom Bialaski, Sun Microsystems; Roger Hartmuller, TIS Labs at Network Associates; Kaowen Liu; Andy Spitzer; Rik Schneider; Jesse St. Laurent; Steve Bellenot; Ray W. Hiltbrand; Jennifer Witham; Gert-Jan Hagenaars; and Casper Dik.

A Practical Guide to Linux® Commands, Editors, and Shell Programming is based in part on two of my previous UNIX books: UNIX System V: A Practical Guide and A Practical Guide to the UNIX System. Many people helped me with those books, and thanks here go to Pat Parseghian, Dr. Kathleen Hemenway, and Brian LaRose; Byron A.
I continue to be grateful to the many people who helped with the early editions of my UNIX books. Special thanks are due to Roger Sippl, Laura King, and Roy Harrington for introducing me to the UNIX system. My mother, Dr. Helen Sobell, provided invaluable comments on the original manuscript at several junctures. Also, thanks go to Isaac Rabinovitch, Professor Raphael Finkel, Professor Randolph Bentson, Bob Greenberg, Professor Udo Pooch, Judy Ross, Dr. Robert Veroff, Dr. Mike Denny, Joe DiMartino, Dr. John Mashey, Diane Schulz, Robert Jung, Charles Whitaker, Don Cragun, Brian Dougherty, Dr. Robert Fish, Guy Harris, Ping Liao, Gary Lindgren, Dr. Jarrett Rosenberg, Dr. Peter Smith, Bill Weber, Mike Bianchi, Scooter Morris, Clarke Echols, Oliver Grillmeyer, Dr. David Korn, Dr. Scott Weikart, and Dr. Richard Curtis.

I take responsibility for any errors and omissions in this book. If you find one or just have a comment, let me know (mgs@sobell.com) and I will fix it in the next printing. My home page (www.sobell.com) contains a list of errors and credits those who found them. It also offers copies of the longer scripts from the book and pointers to many interesting Linux pages.

The GNU/Linux Connection 2

The Heritage of Linux: UNIX 5

What Is So Good About Linux? 6

Overview of Linux 10

Additional Features of Linux 15

The Linux kernel was developed by Finnish undergraduate student Linus Torvalds, who used the Internet to make the source code immediately available to others for free. Torvalds released Linux version 0.01 in September 1991.

The new operating system came together through a lot of hard work. Programmers around the world were quick to extend the kernel and develop other tools, adding functionality to match that already found in both BSD UNIX and System V UNIX (SVR4) as well as new functionality.

The Linux operating system, developed through the cooperation of many, many people around the world, is a product of the Internet and is a free operating system. In other words, all the source code is free. You are free to study it, redistribute it, and modify it. As a result, the code is available free of cost—no charge for the software, source, documentation, or support (via newsgroups, mailing lists, and other Internet resources). As the GNU Free Software Definition (www.gnu.org/philosophy/free-sw.html) puts it:
**Free beer**

"Free software" is a matter of liberty, not price. To understand the concept, you should think of "free" as in "free speech," not as in "free beer."
The Gnu/Linux Connection

An operating system is the low-level software that schedules tasks, allocates storage, and handles the interfaces to peripheral hardware, such as printers, disk drives, the screen, keyboard, and mouse. An operating system has two main parts: the kernel and the system programs. The kernel allocates machine resources, including memory, disk space, and CPU (page 869) cycles, to all other programs that run on the computer. The system programs perform higher-level housekeeping tasks, often acting as servers in a client/server relationship. Linux is the name of the kernel that Linus Torvalds presented to the world in 1991 and that many others have worked on since then to enhance, stabilize, expand, and make more secure.

The History of Gnu/Linux

This section presents some background on the relationship between GNU and Linux.

Fade to 1983

Richard Stallman (www.stallman.org) announces [1] the GNU Project for creating an operating system, both kernel and system programs, and presents the GNU Manifesto, [2] which begins as follows:

GNU, which stands for Gnu's Not UNIX, is the name for the complete UNIX-compatible software system which I am writing so that I can give it away free to everyone who can use it.

Some years later Stallman added a footnote to the preceding sentence when he realized that it was creating confusion:

The wording here was careless. The intention was that nobody would have to pay for "permission" to use the GNU system. But the words don't make this clear, and people often interpret them as saying that copies of GNU should always be distributed at little or no charge. That was never the intent; later on, the manifesto mentions the possibility of companies providing the service of distribution for a profit. Subsequently I have learned to distinguish carefully between "free" in the sense of freedom and "free" in the sense of price. Free software is software that users have the freedom to distribute and change. Some users may obtain copies at no charge, while others pay to obtain copiesand if the funds help support improving the software, so much the better. The important thing is that everyone who has a copy has the freedom to cooperate with others in using it.

In the manifesto, after explaining a little about the project and what has been accomplished so far, Stallman continues:

Why I Must Write GNU

I consider that the golden rule requires that if I like a program I must share it with other people who like it. Software sellers want to divide the users and conquer them, making each user agree not to share with others. I refuse to break solidarity with other users in this way. I cannot in good conscience sign a nondisclosure agreement or a software license agreement. For years I worked within the Artificial Intelligence Lab to resist such tendencies and other inhospitalities, but eventually they had gone too far: I could not remain in an institution where such things are done for me against my will.

So that I can continue to use computers without dishonor, I have decided to put together a sufficient body of
So that I can continue to use computers without dishonor, I have decided to put together a sufficient body of free software so that I will be able to get along without any software that is not free. I have resigned from the AI Lab to deny MIT any legal excuse to prevent me from giving GNU away.

Next Scene, 1991

The GNU Project has moved well along toward its goal. Much of the GNU operating system, except for the kernel, is complete. Richard Stallman later writes:

By the early '90s we had put together the whole system aside from the kernel (and we were also working on a kernel, the GNU Hurd,[3] which runs on top of Mach[4]). Developing this kernel has been a lot harder than we expected, and we are still working on finishing it.[5]

. . . [M]any believe that once Linus Torvalds finished writing the kernel, his friends looked around for other free software, and for no particular reason most everything necessary to make a UNIX-like system was already available.

What they found was no accident—it was the GNU system. The available free software[6] added up to a complete system because the GNU Project had been working since 1984 to make one. The GNU Manifesto had set forth the goal of developing a free UNIX-like system, called GNU. The Initial Announcement of the GNU Project also outlines some of the original plans for the GNU system. By the time Linux was written, the GNU system was almost finished.[7]

Today the GNU "operating system" runs on top of the FreeBSD (www.freebsd.org) and NetBSD (www.netbsd.org) kernels with complete Linux binary compatibility and on top of Hurd pre-releases and Darwin (developer.apple.com/darwin) without this compatibility.

The Code is Free

The tradition of free software dates back to the days when UNIX was released to universities at nominal cost, which contributed to its portability and success. This tradition died as UNIX was commercialized and manufacturers regarded the source code as proprietary, making it effectively unavailable. Another problem with the commercial versions of UNIX related to their complexity. As each manufacturer tuned UNIX for a specific architecture, it became less portable and too unwieldy for teaching and experimentation.

MINIX

Two professors created their own stripped-down UNIX look-alikes for educational purposes: Doug Comer created XINU (www.cs.purdue.edu/research/xinu.html) and Andrew Tanenbaum created MINIX (www.cs.vu.nl/~ast/minix.html). Linus Torvalds created Linux to counteract the shortcomings in MINIX. Every time there was a choice between code simplicity and efficiency/features Tanenbaum chose simplicity (to make it easy to teach with MINIX), which meant that this system lacked many of features people wanted. Linux goes in the
You can obtain Linux at no cost over the Internet. You can also obtain the GNU code via the U.S. mail at a modest cost for materials and shipping. You can support the Free Software Foundation by buying the same (GNU) code in higher-priced packages, and you can buy commercial packaged releases of Linux (called distributions) that include installation instructions, software, and support.

GPL

Linux and GNU software are distributed under the terms of the GNU General Public License (GPL, www.gnu.org/licenses/licenses.html). The GPL says you have the right to copy, modify, and redistribute the code covered by the agreement. If you redistribute the code, you must also distribute the same license with the code, making the code and the license inseparable. If you get the source code off the Internet for an accounting program that is under the GPL, modify the code, and then redistribute an executable version of the program, you must also distribute the modified source code and the GPL agreement with it. Because this is the reverse of the way a normal copyright works (it gives rights instead of limiting them), it has been termed a copyleft. (This paragraph is not a legal interpretation of the GPL; it simply gives you an idea of how it works. Refer to the GPL itself when you want to make use of it.)

Have fun!

Two key words for Linux are "Have Fun!" These words pop up in prompts and documentation. The UNIX→now Linux→culture is steeped in humor that can be seen throughout the system. For example, less is more→GNU has replaced the UNIX paging utility named more with an improved utility named less. The utility to view PostScript documents is named ghostscript, and one of several replacements for the vi editor is named elvis. While machines with Intel processors have "Intel Inside" logos on their outside, some Linux machines sport "Linux Inside" logos. And Torvalds himself has been seen wearing a T-shirt bearing a "Linus Inside" logo.
The Heritage of Linux: Unix

The UNIX system was developed by researchers who needed a set of modern computing tools to help them with their projects. The system allowed a group of people working together on a project to share selected data and programs while keeping other information private.

Universities and colleges played a major role in furthering the popularity of the UNIX operating system through the "four-year effect." When the UNIX operating system became widely available in 1975, Bell Labs offered it to educational institutions at nominal cost. The schools, in turn, used it in their computer science programs, ensuring that computer science students became familiar with it. Because UNIX was such an advanced development system, the students became acclimated to a sophisticated programming environment. As these students graduated and went into industry, they expected to work in a similarly advanced environment. As more of them worked their way up the ladder in the commercial world, the UNIX operating system found its way into industry.

In addition to introducing students to the UNIX operating system, the Computer Systems Research Group (CSRG) at the University of California at Berkeley made significant additions and changes to it. In fact, it made so many popular changes that one version of the system is called the Berkeley Software Distribution (BSD) of the UNIX system (or just Berkeley UNIX). The other major version is UNIX System V (SVR4), which descended from versions developed and maintained by AT&T and UNIX System Laboratories.
What is so good about Linux?

In recent years Linux has emerged as a powerful and innovative UNIX work-alike. Its popularity is surpassing that of its UNIX predecessors. Although it mimics UNIX in many ways, the Linux operating system departs from UNIX in several significant ways: The Linux kernel is implemented independently of both BSD and System V, the continuing development of Linux is taking place through the combined efforts of many capable individuals throughout the world, and Linux puts the power of UNIX within easy reach of business and personal computer users. Using the Internet, today's skilled programmers submit additions and improvements to the operating system to Linus Torvalds, GNU, or one of the other authors of Linux.

Applications

A rich selection of applications is available for Linux—both free and commercial—as well as a wide variety of tools: graphical, word processing, networking, security, administration, Web server, and many others. Large software companies have recently seen the benefit in supporting Linux and have now on-staff programmers whose job it is to design and code the Linux kernel, GNU, KDE, or other software that runs on Linux. For example, IBM (www.ibm.com/linux) is a major Linux supporter. Linux conforms increasingly more closely to POSIX standards, and some distributions and parts of others meet this standard. (See "Standards" on page 8 for more information.) These facts mean that Linux is becoming more mainstream and is respected as an attractive alternative to other popular operating systems.

Peripherals

Another aspect of Linux that appeals to users is the amazing range of peripherals that is supported and the speed with which support for new peripherals emerges. Linux often supports a peripheral or interface card before any company does. Unfortunately some types of peripherals—particularly proprietary graphics cards—lag in their support because the manufacturers do not release specifications or source code for drivers in a timely manner, if at all.

Software

Also important to users is the amount of software that is available—not just source code (which needs to be compiled) but also prebuilt binaries that are easy to install and ready to run. These include more than free software. Netscape, for example, has been available for Linux from the start and included Java support before it was available from many commercial vendors. Now its sibling Mozilla is also a viable browser, mail client, and newsreader, performing many other functions as well.

Platforms

Linux is not just for Intel-based platforms but has been ported to and runs on the Power PC—including Apple computers (ppclinux), the Compaq's (née Digital Equipment Corporation) Alpha-based machines, MIPS-based machines, Motorola's 68K-based machines, and IBM's S/390. Nor is Linux just for single-processor machines: As of version 2.0, it runs on multiple processor machines (SMPs). As of version 2.5.2, Linux includes an O(1) scheduler, which dramatically increases scalability on SMP systems.

Emulators

Linux supports programs, called emulators, that run code intended for other operating systems. By using emulators you can run some DOS, Windows, and Macintosh programs under Linux. Wine (www.winehq.com) is an open-source implementation of the Windows API on top of X and UNIX/Linux; QEMU (fabrice.bellard.free.fr/qemu) is a CPU-only emulator that executes x86 Linux binaries on non-x86 Linux systems.
Why Linux Is Popular With Hardware Companies And Developers

Two trends in the computer industry set the stage for the popularity of UNIX and Linux. First, advances in hardware technology created the need for an operating system that could take advantage of available hardware power. In the mid-1970s, minicomputers began challenging the large mainframe computers because, in many applications, minicomputers could perform the same functions less expensively. More recently, powerful 64-bit processor chips, plentiful and inexpensive memory, and lower-priced hard disk storage have allowed hardware companies to install multiuser operating systems on desktop computers.

Proprietary operating systems

Second, with the cost of hardware continually dropping, hardware manufacturers can no longer afford to develop and support proprietary operating systems. A proprietary operating system used to be written and owned by the manufacturer of the hardware (for example, DEC/Compaq owns VMS). Today's manufacturers need a generic operating system that they can easily adapt to their machines.

Generic operating systems

A generic operating system is written outside of the company manufacturing the hardware and is sold (UNIX, Windows) or given (Linux) to the manufacturer. Linux is a generic operating system because it runs on different types of hardware produced by different manufacturers. Of course, if manufacturers can pay only for development and avoid per-unit costs (as they have to pay to Microsoft for each copy of Windows they sell), developers are much better off. In turn, software developers need to keep the prices of their products down; they cannot afford to convert their products to run under many different proprietary operating systems. Like hardware manufacturers, software developers need a generic operating system.

Although the UNIX system once met the needs of hardware companies and researchers for a generic operating system, over time it has become more proprietary as each manufacturer has added support for specialized features and introduced new software libraries and utilities.

Linux emerged to serve both needs. It is a generic operating system that takes advantage of available hardware power.

Linux Is Portable

A portable operating system is one that can run on many different machines. More than 95 percent of the Linux operating system is written in the C programming language, and C is portable because it is written in a higher-level, machine-independent language. (The C compiler is written in C.)

Because Linux is portable, it can be adapted (ported) to different machines and can meet special requirements. For example, Linux is used in embedded computers, such as the ones found in cellphones, PDAs, and the cable boxes on top of many TVs. The file structure takes full advantage of large, fast hard disks. Equally important, Linux was originally designed as a multiuser operating system—it was not modified to serve several users as an afterthought. Sharing the computer's power among many users and giving them the ability to share data and programs are central features of the system.

Because it is adaptable and takes advantage of available hardware, Linux now runs on many different microprocessor-based systems as well as mainframes. The popularity of the microprocessor-based hardware drives Linux; these microcomputers are getting faster all the time, at about the same price point. Linux on a fast microcomputer has become good enough to displace workstations on many desktops. Linux benefits both users,
who do not like having to learn a new operating system for each vendor's hardware, and the system administrators, who like having a consistent software environment.

The advent of a standard operating system has aided the development of the software industry. Now software manufacturers can afford to make one version of a product available on machines from different manufacturers.

**Standards**

Individuals from companies throughout the computer industry have joined together to develop the POSIX (Portable Operating System Interface for computer Environments) standard, which is based largely on the UNIX System V Interface Definition (SVID) and other earlier standardization efforts. These efforts have been spurred by the U.S. government, which needs a standard computing environment to minimize its training and procurement costs. Now that these standards are gaining acceptance, software developers are able to develop applications that run on all conforming versions of UNIX, Linux, and other operating systems.

**The C Programming Language**

Ken Thompson wrote the UNIX operating system in 1969 in PDP-7 assembly language. Assembly language is machine dependent: Programs written in assembly language work on only one machine or, at best, one family of machines. The original UNIX operating system therefore could not easily be transported to run on other machines (it was not portable).

To make UNIX portable, Thompson developed the B programming language, a machine-independent language, from the BCPL language. Dennis Ritchie developed the C programming language by modifying B and, with Thompson, rewrote UNIX in C in 1973. The revised operating system could be transported more easily to run on other machines.

That development marked the start of C. Its roots reveal some of the reasons why it is such a powerful tool. C can be used to write machine-independent programs. A programmer who designs a program to be portable can easily move it to any computer that has a C compiler. C is also designed to compile into very efficient code. With the advent of C, a programmer no longer had to resort to assembly language to get code that would run well (that is, quickly, although an assembler will always generate more efficient code than a high-level language).

C is a good systems language. You can write a compiler or an operating system in C. It is highly structured but is not necessarily a high-level language. C allows a programmer to manipulate bits and bytes, as is necessary when writing an operating system. But it also has high-level constructs that allow efficient, modular programming.

In the late 1980s the American National Standards Institute (ANSI) defined a standard version of the C language, commonly referred to as ANSI C or C89 (for the year the standard was published). Ten years later the C99 standard was published; it is mostly supported by the GNU Project's C compiler (named gcc). The original version of the language is often referred to as Kernighan & Ritchie (or K&R) C, named for the authors of the book that first described the C language.

Another researcher at Bell Labs, Bjarne Stroustrup, created an object-oriented programming language named C++, which is built on the foundation of C. Because object-oriented programming is desired by many employers today, C++ is preferred over C in many environments. The GNU Project's C compiler and its C++ compiler (g++) are integral parts of the Linux operating system.
**Overview of Linux**

The Linux operating system has many unique and powerful features. Like other operating systems, Linux is a control program for computers. But like UNIX, it is also a well-thought-out family of utility programs (Figure 1-1) and a set of tools allowing users to connect and use these utilities to build systems and applications.

![Figure 1-1. A layered view of the Linux operating system](image)

**Linux Has a Kernel Programming Interface**

The heart of the Linux operating system is the Linux kernel, which is responsible for allocating the computer's resources and scheduling user jobs so that each one gets its fair share of system resources, including access to the CPU; peripheral devices, such as disk, DVD, and CD-ROM storage; printers; and tape drives. Programs interact with the kernel through system calls, special functions with well-known names. A programmer can use a single system call to interact with many kinds of devices. For example, there is one `write` system call, not many device-specific ones. When a program issues a `write` request, the kernel interprets the context and passes the request to the appropriate device. This flexibility allows old utilities to work with devices that did not exist when the utilities were originally written. It also makes it possible to move programs to new versions of the operating system without rewriting them (provided that the new version recognizes the same system calls).

**Linux Can Support Many Users**

Depending on the hardware and what types of tasks the computer performs, a Linux system can support from 1 to more than 1,000 users, each concurrently running a different set of programs. The per-user cost of a computer that can be used by many people at the same time is less than that of a computer that can be used by only a single person at a time. It is less because one person cannot generally use all the resources a computer has to offer. No one can keep the printers going constantly, keep all the system memory in use, keep the disks busy reading and writing, keep the Internet connection in use, and keep all the terminals busy at the same time. A multiuser operating system allows many people to use these system resources almost simultaneously. The use of costly resources can be maximized, and the cost per user can be minimized. These are the primary objectives of a multiuser operating system.

**Linux Can Run Many Tasks**
Linux is a fully protected multitasking operating system, allowing each user to run more than one job at a time. Processes can communicate with one another but remain fully protected from one another, just as the kernel is protected from all processes. You can run several jobs in the background while giving all your attention to the job being displayed on your screen, and you can switch back and forth between jobs. If you are running the X Window System (page 15), you can run different programs in different windows on the same screen and watch all of them. This capability ensures that users can be more productive.

**Linux Provides a Secure Hierarchical Filesystem**

A *file* is a collection of information, such as text for a memo or report, an accumulation of sales figures, an image, a song, or an executable program. Each file is stored under a unique identifier on a storage device, such as a hard disk. The Linux filesystem provides a structure whereby files are arranged under *directories*, which are like folders or boxes. Each directory has a name and can hold other files and directories. Directories, in turn, are arranged under other directories, and so forth, in a treelike organization. This structure helps users keep track of large numbers of files by grouping related files into directories. Each user has one primary directory and as many subdirectories as required (Figure 1-2).

**Figure 1-2. The Linux filesystem structure**

![Linux Filesystem Diagram](image)

**Standards**

With the idea of making life easier for system administrators and software developers, a group got together over the Internet and developed the Linux Filesystem Standard (FSSTND), which has since evolved into the Linux Filesystem Hierarchy Standard (FHS). Before this standard was adopted, key programs were located in different places in different Linux distributions. Today you can sit down at a Linux system and know where to expect to find any given standard program.

**Links**
A link allows a given file to be accessed by means of two or more different names. (Windows uses the term shortcut instead of link.) The alternative names can be located in the same directory as the original file or in another directory. Links can be used to make the same file appear in several users' directories, enabling them to share the file easily.

Security

Like most multiuser operating systems, Linux allows users to protect their data from access by other users. It also allows users to share selected data and programs with certain other users by means of a simple but effective protection scheme. This level of security is provided by file access permissions, which limit which users can read from, write to, or execute a file. Access Control Lists (ACLs) have recently been added to the Linux kernel. ACLs give users and administrators finer-grained control over file access permissions.

The Shell: Command Interpreter And Programming Language

In a textual environment, the shell—the command interpreter—acts as an interface between you and the operating system. When you enter a command on the screen, the shell interprets the command and calls the program you want. A number of shells are available for Linux including these two common ones:

- The Bourne Again Shell (bash), an enhanced version of the Bourne Shell, one of the original UNIX shells
- The TC Shell (tcsh), an enhanced version of the C Shell, developed as part of BSD UNIX

Because users often prefer different shells, multiuser systems can have a number of different shells in use at any given time. The choice of shells demonstrates one of the powers of the Linux operating system: the ability to provide a customized user interface.

Besides performing its function of interpreting commands from a keyboard and sending them to the operating system, the shell is a high-level programming language. Shell commands can be arranged in a file for later execution. Linux calls these files shell scripts; DOS and Windows call them batch files. Their flexibility allows users to perform complex operations with relative ease, often by using rather short commands, and to build with surprisingly little effort elaborate programs that perform highly complex operations.

Filename Generation

When you are typing commands to be processed by the shell, you can construct patterns using characters that have special meanings to the shell. The characters are called wildcard characters. These patterns represent a kind of shorthand: Rather than typing in complete filenames users can type in patterns, and the shell will expand them into matching filenames. These patterns are called ambiguous file references. An ambiguous file reference can save you the effort of typing a long filename or a long series of similar filenames. It can also be useful when you know only part of a filename or cannot remember its exact spelling.

Device-Independent Input And Output

Redirection

Devices (such as a printer or terminal) and disk files all appear as files to Linux programs. When you give a command to the Linux operating system, you can instruct it to send the output to any one of several devices or files.
This diversion is called output redirection.

In a similar manner a program's input that normally comes from a keyboard can be redirected so that it comes from a disk file instead. Input and output are *device independent*; they can be redirected to or from any appropriate device.

As an example, the `cat` utility normally displays the contents of a file on the screen. When you run a `cat` command, you can easily redirect its output to go to a disk file instead of the screen.

**Shell Functions**

One of the most important features of the shell is that users can use it as a programming language. Because the shell is an interpreter, it does not compile programs written for it but rather interprets them each time they are loaded from the disk. Loading and interpreting programs can be time-consuming.

Many shells, including the Bourne Again Shell, include shell functions that the shell holds in memory so that it does not have to read them from the disk each time you want to execute them. The shell also keeps functions in an internal format so that it does not have to spend as much time interpreting them.

**Job Control**

*Job control* is a shell feature that allows users to work on several jobs at once, switching back and forth between them as desired. When you start a job it is frequently in the foreground, so it is connected to your terminal. Using job control, you can move the job you are working with into the background and continue running it there while working on or observing another job in the foreground. If a background job then needs your attention, you can move it into the foreground so that it is once again attached to the terminal. The concept of job control originated with BSD UNIX, where it appeared in the C Shell.

**A Large Collection Of Useful Utilities**

Linux includes a family of several hundred utility programs, often referred to as *commands*. These utilities perform functions that are universally required by users. An example is sort. The `sort` utility puts lists (or groups of lists) in alphabetical or numerical order and can be used to sort by part number, last name, city, ZIP code, telephone number, age, size, cost, and so forth. The `sort` utility is an important programming tool and is part of the standard Linux system. Other utilities allow users to create, display, print, copy, search, and delete files, as well as to edit, format, and typeset text. The `man` (for manual) and `info` utilities provide online documentation of Linux itself.

**Interprocess Communication**

**Pipes and filters**

Linux allows users to establish both pipes and filters on the command line. A *pipe* sends the output of one program to another program as input. A *filter* is a special form of a pipe that processes a stream of input data to yield a stream of output data. A filter processes another program's output, altering it as a result. The filter's output then becomes input to another program.

Pipes and filters frequently join utilities to perform a specific task. For example, you can use a pipe to send the output of the `cat` utility to `sort`, a filter. You can then use another pipe to send the output of `sort` to a third
utility, `1pr`, that sends the data to a printer. Thus, in one command line, you can use three utilities together to sort and print a file.

**System Administration**

On a Linux system the system administrator is frequently the owner and only user of the system. This person has many responsibilities. The first responsibility may be to set up the system and install the software.

Once the system is up and running, the system administrator is responsible for downloading and installing software (including upgrading the operating system), backing up and restoring files, and managing such system facilities as printers, terminals, servers, and a local network. The system administrator is also responsible for setting up accounts for new users on a multiuser system, bringing the system up and down as needed, and taking care of any problems that arise.
Additional Features of Linux

The developers of Linux included features from BSD, System V, and Sun Microsystems' Solaris, as well as new features in their operating system. Although most of the tools found on UNIX exist for Linux, in many cases these tools have been replaced by more modern counterparts. The following sections describe many of the popular tools and features available under Linux.

Guis: Graphical User Interfaces

The X Window System (also called X) was developed in part by researchers at the Massachusetts Institute of Technology and provides the foundation for the GUIs available with Linux. Given a terminal or workstation screen that supports X, a user can interact with the computer through multiple windows on the screen, display graphical information, or use special-purpose applications to draw pictures, monitor processes, or preview formatted output. X is an across-the-network protocol that allows a user to open a window on a workstation or computer system that is remote from the CPU generating the window.

Desktop manager

Usually two layers run under X: a desktop manager and a window manager. A desktop manager is a picture-oriented user interface that enables you to interact with system programs by manipulating icons instead of typing the corresponding commands to a shell. GNOME (www.gnome.org) and KDE (www.kde.org) are the most popular desktop managers.

Window manager

A window manager is a program that runs under the desktop manager and allows you to open and close windows, start programs running, and set up a mouse so it does different things depending on how and where you click. The window manager also gives the screen its personality. Microsoft Windows allows you to change the color of key elements in a window, but a window manager under X allows you to change the overall look and feel of your screen: change the way a window looks and works (by giving it different borders, buttons, and scrollbars), set up virtual desktops, create menus, and more.

Several popular window managers run under X and Linux, including Metacity (default under GNOME) and kwin (default under KDE). Other window managers, such as Sawfish and WindowMaker, are also available.

(Inter)Networking Utilities

Linux network support includes many valuable utilities that enable you to access remote systems over a variety of networks. In addition to sending email to users on other systems, you can access files on disks mounted on other computers as if they were located on the local system, make your files available to other systems in a similar manner, copy files back and forth, run programs on remote systems while displaying the results on the local system, and perform many other operations across local area networks (LANs) and wide area networks (WANs), including the Internet.

Layered on top of this network access are a wide range of application programs that extend the computer's resources around the globe. You can carry on conversations with people throughout the world, gather information on a wide variety of subjects, and download new software over the Internet quickly and reliably.

Software Development
One of Linux's major strengths is its rich software development environment. You can find compilers and interpreters for many computer languages. Besides C and C++, languages available for Linux include Ada, Fortran, Java, Lisp, Pascal, Perl, and Python among many others. The **bison** utility generates parsing code that makes it easier to write programs to build compilers (tools that parse files containing structured information). The **flex** utility generates scanners, or code that recognizes lexical patterns in text. The **make** utility and GNU's automatic configuration utility (**configure**) make it easy to manage complex development projects. Source code management systems, such as CVS, simplify version control. Several debuggers, including **ups** and **gdb**, help in tracking down and repairing software defects. The GNU C compiler (**gcc**) works with the **gprof** profiling utility to help programmers identify potential bottlenecks in a program's performance. The C compiler includes options to perform extensive checking of C code that can make the code more portable and reduce debugging time.
Chapter Summary

The Linux operating system grew out of the UNIX heritage to become a popular alternative to traditional systems (that is, Windows) available for microcomputer (PC) hardware. UNIX users will find a familiar environment in Linux. Distributions of Linux contain the expected complement of UNIX utilities, contributed by programmers around the world, including the set of tools developed as part of the GNU Project. The Linux community is committed to the continued development of this system. Support for new microcomputer devices and features is added soon after the hardware becomes available, and the tools available on Linux continue to be refined. With many commercial software packages available to run on Linux platforms and many hardware manufacturers offering Linux on their systems, it is clear that the system has evolved well beyond its origin as an undergraduate project to become an operating system of choice for academic, commercial, professional, and personal use.
Exercises

1. What is free software? List three characteristics of free software.

2. Why is Linux popular? Why is it popular in academia?

3. What are multiuser systems? Why are they successful?

4. What is the Free Software Foundation/GNU? What is Linux? Which parts of the Linux operating system did each provide? Who else has helped build and refine this operating system?

5. In what language is Linux written? What does the language have to do with the success of Linux?

6. What is a utility program?

7. What is a shell? How does it work with the kernel? With the user?

8. How can you use utility programs and a shell to create your own applications?

9. Why is the Linux filesystem referred to as hierarchical?

10. What is the difference between a multiprocessor and a multiprocessing system?

11. Give an example of when you would want to use a multiprocessing system.

12. Approximately how many people wrote Linux? Why is this unique?

13. What are the key terms of the GNU General Public License (GPL)?
Part I: The Linux Operating System

CHAPTER 2 Getting Started
CHAPTER 3 Command Line Utilities
CHAPTER 4 The Linux Filesystem
CHAPTER 5 The Shell
Chapter 2. Getting Started

IN THIS CHAPTER

Conventions Used in This Book 22

Logging In 24

Logging In Remotely: Terminal Emulation, ssh, and telnet 25

Curbing Your Power: Superuser Access 28

Getting the Facts: Where to Find Documentation 29

The help Option 29

man: Displays the System Manual 30

info: Displays Information About Utilities 32

HOWTOs: Finding Out How Things Work 34

What to Do If You Cannot Log In 36

Changing Your Password 37

One way or another you are sitting in front of a screen that is connected to a computer that is running Linux. You may be working with a graphical user interface (GUI) or a textual interface. This book is about the textual, or command line, interface to Linux. If you are working with a GUI, you will need to use a terminal emulator such as xterm, Konsole, or GNOME Terminal, to follow along with the examples in this book.

This chapter starts with a discussion of the typographical conventions used in this book, followed by a section on logging in on the system. Next there is a brief reminder about the powers of Superuser (root) and how to avoid making mistakes that will make your system inoperable or hard to work with. The chapter continues with a discussion about where to find more information about Linux. It concludes with additional information on logging in, including how to change your password.

While heeding the warning about the dangers of misusing the powers of Superuser on page 29, feel free to experiment with your system: Give commands, create files, follow the examples in this book, and have fun.
Conventions Used in This Book

This book uses conventions to make its explanations shorter and clearer. The following paragraphs describe these conventions.

Text and examples

The text is set in this type, whereas examples are shown in a monospace font (also called a fixed-width font):

```
$ cat practice
This is a small file I created with a text editor.
```

The next paragraph explains why part of the first line is in a bold typeface.

Items you enter

Everything you enter at the keyboard is shown in a bold typeface: Within the text, this bold typeface is used; within examples and screens, this one is used. In the previous example, the dollar sign ($) on the first line is a prompt that Linux displays, so it is not bold; the remainder of the first line is entered by a user, so it is bold.

Utility names

Names of utilities are printed in this bold sans serif typeface. This book references the emacs editor and the ls utility or ls command (or just ls), but instructs you to enter ls a on the command line. The text distinguishes between utilities, which are programs, and the instructions you give on the command line to invoke the utilities.

Filenames

Filenames appear in a bold typeface. Examples are memo5, letter.1283, and reports. Filenames may include uppercase and lowercase letters; however, Linux is case sensitive (866), so memo5, MEMO5, and Memo5 name three different files.

Character strings

Within the text, characters and character strings are marked by putting them in a bold typeface. This convention avoids the need for quotation marks or other delimiters before and after a string. An example is the following string, which is displayed by the passwd utility: Sorry, passwords do not match.

Keys and characters

This book uses SMALL CAPS for three kinds of items:

- Important keyboard keys, such as the SPACE bar and the RETURN, [1] ESCAPE, and TAB keys.
Different keyboards use different keys to move the cursor (870) to the beginning of the next line. This book always refers to the key that ends a line as the RETURN key. Your keyboard may have a RET, NEWLINE, Enter, RETURN, or other key. Some keyboards have a key with a bent arrow on it. (The key with the bent arrow is not an arrow key. Arrow keys have straight shafts.) Use the corresponding key on your keyboard each time this book asks you to press RETURN.

- The characters that keys generate, such as the SPACEs generated by the SPACE bar.
- Keyboard keys that you press with the CONTROL key, such as CONTROL-D. (Even though D is shown as an uppercase letter, you do not have to press the SHIFT key. Enter CONTROL-D by holding down the CONTROL key and pressing d.)

Prompts and RETURNs

Most examples include the shell prompt—the signal that Linux is waiting for a command—as a dollar sign ($). The prompt is not in boldface, because you do not enter it. Do not type the prompt on the keyboard when you are experimenting with examples from this book. If you do, the examples will not work.

Examples omit the RETURN keystroke that you must use to execute them. An example of a command line is

$ vim memo.1204

To use this example as a model for running the vim editor, give the command vim memo.1204 and press the RETURN key. (Press ESCAPE ZZ to exit from vim; see page 141 for a vim tutorial.) This method of entering commands makes the examples in the book correspond to what appears on your screen.

Definitions

All entries marked with FOLDOC are courtesy of Denis Howe, editor of the Free Online Dictionary of Computing (www.foldoc.org), and are used with permission. This site is an ongoing work containing not just definitions but also anecdotes and trivia.
optional

Passages marked as optional are not central to the ideas presented in the chapter but often involve more challenging concepts. A good strategy when reading a chapter is to skip the optional sections and then return to them when you are comfortable with the main ideas presented in the chapter. This is an optional paragraph.

URLs (Web addresses)

Web addresses, or URLs, have an implicit http:// prefix, unless ftp:// or https:// is shown. You do not normally need to specify a prefix when the prefix is http://, but you must use a prefix from a browser when you specify an FTP or secure HTTP site. Thus you can specify a URL in a browser exactly as shown in this book.

Tip, Caution, and Security boxes

The following boxes highlight information that may be helpful while you are using or administrating a Linux system.

**tip: This is a tip box**

A tip box may help you avoid repeating a common mistake or may point toward additional information.

**caution: This box warns you about something**

A caution box warns you about a potential pitfall.

**security: This box marks a security note**

A security box highlights a potential security issue. These notes are usually for system administrators but some apply to all users.
Logging In

To log in on a terminal, terminal emulator, or other text-based device, enter your username and password in response to the system prompts. If you are using a terminal (905) and your screen does not display login:, check whether the terminal is plugged in and turned on, and then press the RETURN key a few times. If login: still does not appear, try pressing CONTROL-Q. If you are using a workstation (910), make sure it is running. Run ssh, telnet, or whatever communications/emulation software you have to log in on the system. Try logging in, making sure that you enter your username and password as they were specified when your account was set up; the routine that verifies the username and password is case sensitive. Like most systems, Linux does not echo your password when you enter it.

**tip: Make sure TERM is set correctly**

The TERM shell variable establishes the pseudographical characteristics of a character-based terminal or terminal emulator. Typically TERM is set for you; you do not have to set it manually. If things on the screen do not look right, refer to "Specifying a Terminal" on page 844.

Logging In From a Terminal

The following example shows what it looks like when you log in from a terminal. Max is logging in on the bravo system.

```
bravo login: max
Password:
Last login: Tue Mar  1 19:50:38 from kudos
[max@bravo max]$
```

After you log in, the shell prompt (or just prompt) appears, indicating that you have successfully logged in. It shows that the system is ready for you to give it a command. The shell prompt line may be preceded by one or two short messages called the message of the day (or motd) and issue. These messages generally identify the version of Linux that is running, along with local messages placed in either the /etc/motd or the /etc/issue file.

**security: Did you log in last?**

Immediately after you log in, the system may display information about the last login on this account, showing when it took place and where it originated. You can use this information to see whether anyone else may have accessed this account since you last used it. Perhaps an unauthorized user has learned your password and has logged in as you. In the interest of security, advise the system administrator of the circumstances that made you suspicious and change your password (page 37).

The usual prompt is a dollar sign ($). Do not be concerned if you have a different prompt; the examples in this book will work regardless of what your prompt looks like. In the previous example the $ prompt (last line) is preceded by the username (max), an at sign (@), the system name (bravo), and the name of the directory Max is working in (max). For information on how to change your prompt, refer to page 286 (bash) or page 363 (tcsh).

Logging In Remotely: Terminal Emulation, ssh, and telnet
When you are not using the console, a terminal, or another device connected directly to the Linux system you are logging in on, you are probably connected to Linux using terminal emulation software on another system. This software runs on your computer, connects to the Linux system via a network (e.g., Ethernet, asynchronous phone line, PPP), and allows you to log in on the Linux system.

When you log in via a dial-up line, the connection is straightforward: You instruct the emulator program to contact the computer, it dials the phone, and you get a login prompt from the remote system. When you log in via a directly connected network, you use telnet (not secure, page 792) or ssh (secure, page 773) to connect to the remote system. One of the reasons that telnet is not secure is that it sends your username and password over the network in cleartext (867) when you log in, allowing someone to capture your login information and log in on your account. The ssh utility encrypts all information it sends over the network and, if available, is a better choice than telnet.

From an Apple, PC, UNIX, or other machine, give the command ssh or telnet, followed by the name or IP address (882) of the machine you want to log in on. Following is an example of logging in using ssh:

```
$ ssh bravo

max@bravo's password:

Permission denied, please try again.

max@bravo's password:

Last login: Wed Mar  2 21:21:49 2005 from bravo.example.com

[max@bravo max]$ 
```

In the preceding example the user mistyped his password, received an error message and another prompt, and retyped the password correctly.
Working with the Shell

When you log in and are working in a textual (non-graphical) environment, and when you are using a terminal emulator window in a graphical environment, you are using the shell as a command interpreter. That is, the shell displays a prompt, you type a command, and the shell executes the command and displays another prompt.

This section tells you how to identify the shell you are using and explains the keystrokes you can use to correct mistakes on the command line. It covers how to abort a running command and briefly discusses how to edit a command line. Several chapters of this book are dedicated to shells: **Chapter 5** introduces shells, **Chapter 8** goes into more detail about the Bourne Again Shell with some coverage of the TC Shell, **Chapter 9** covers the TC Shell exclusively, and **Chapter 11** discusses writing programs (shell scripts) using the Bourne Again Shell.

Which Shell Are You Running?

This book discusses both the Bourne Again Shell (**bash**) and the TC Shell (**tcsh**). You are probably running **bash**, but you may be running **tcsh** or another shell such as the Z Shell (**zsh**). You can identify the shell you are running by using the **ps** utility. Type **ps** in response to the shell prompt and press RETURN.

```
$ ps

   PID  TTY          TIME   CMD
  2402 pts/5    00:00:00 bash
  7174 pts/5    00:00:00 ps
```

This command shows that you are running two utilities or commands: **bash** and **ps**. If you are running **tcsh**, **ps** will display **tcsh** instead of **bash**. If you are running a different shell, **ps** will display its name.

Correcting Mistakes

This section explains how to correct typographical and other errors you may make while you are logged in on a character-based display. Because the shell does not begin to interpret the command line or other text until you press RETURN, you can correct typing mistakes before you press that key.

You can correct typing mistakes in several ways: You can erase one character at a time, back up a word at a time, or back up to the beginning of the command line in one step. After you press RETURN, it is too late to correct a mistake. You must either wait for the command to run to completion or abort execution of the program (page 27).

Erasing a Character

While entering characters from the keyboard, you can back up and erase a mistake by pressing the *erase key* once for each character you want to delete. The erase key backs over as many characters as you wish. Usually it will not back up past the beginning of the line.

The default erase key is BACKSPACE. If this key does not work, try DELETE or CONTROL-H. If these keys do not work, give the following command to set the erase and line kill keys (see "Deleting a Line" on page 27) to their defaults:
\$ stty ek

For information on changing which key erases characters, refer to page 781.

**tip: CONTROL-Z suspends a program**

Although not a way of correcting a mistake, you may press the suspend key (typically CONTROL-Z) by mistake and wonder what happened (you will see a message containing the word **Stopped**). You have just stopped the job you were running, using job control (page 271). Give the command `fg` to continue your job in the foreground, and you should return to where you were before you pressed the suspend key. For more information refer to "bg: Sends a Job to the Background: Sends a Job to the Background" on page 273.

**Deleting a Word**

You can delete a word you entered by pressing CONTROL-W. A word is any sequence of characters that does not contain a SPACE or TAB. When you press CONTROL-W, the cursor moves left to the beginning of the current word (as you are entering a word) or the previous word (when you have just entered a SPACE or TAB), removing the word it passes over.

**Deleting a Line**

Any time before you press RETURN, you can delete a line you are entering by pressing the line kill key, also called the kill key. When you press this key, the cursor moves to the left, erasing characters as it goes, back to the beginning of the line. The default line kill key is CONTROL-U. If this key does not work, try CONTROL-X. If neither key works, give the following command to set the erase and line kill keys to their defaults:

\$ stty ek

For information on changing which key deletes a line, refer to page 781.

**Aborting Execution**

Sometimes you may want to terminate a running program. For example, a Linux program may be performing a lengthy task such as displaying the contents of a file that is several hundred pages long or copying a file that is not the one you meant to copy.

To terminate a program from a character-based display, press the interrupt key (CONTROL-C or sometimes DELETE or DEL). When you press this key, the Linux operating system sends a terminal interrupt signal both to the program you are running and to the shell. Exactly what effect this signal has depends on the program. Some programs stop execution immediately; others ignore the signal. Some programs take other actions. When it receives a terminal interrupt signal, the shell displays a prompt and waits for another command. For information on changing which key aborts execution, refer to page 781.

If these methods do not terminate the program, try stopping the program with the suspend key (typically CONTROL-Z), giving the `jobs` command to verify the job number of the program, and using `kill` to abort the
program. The job number is the number within the brackets at the left end of the line that `jobs` displays ([1]). The `kill` command sends a signal to the job specified as its argument. You must precede the job number with a percent sign (\%1):

```
$ bigjob ^Z
[1]+ Stopped bigjob
$ jobs
[1]+ Stopped bigjob
$ kill %1

[1]+ Stopped bigjob
$ RETURN
[1]+ Killed bigjob
```

By default `kill` sends a software termination signal ([`TERM`]). When this signal does not work, try using a `kill` ([`KILL`]) signal:

```
$ kill -KILL %1
```

A running program cannot ignore a kill signal; it is sure to abort the program. The `kill` command returns a prompt; press RETURN again to see the confirmation message. For more information on job control, refer to "Running a Program in the Background" on page 125. For a list of signals, see Table 11-5 on page 494.

Repeating/Editing Command Lines

To repeat a previous command on the command line, press the UP ARROW key. Each time you press UP ARROW, you see an earlier command line. To reexecute the displayed command line, press RETURN. Press DOWN ARROW to browse through the command lines in the other direction.

The RIGHT and LEFT ARROW keys move the cursor back and forth along the displayed command line. At any point along the command line, you can add characters by typing. Use the erase key to remove characters from the command line.

For more complex command line editing, see page 297 (`bash`) and page 353 (`tcsh`).
**Curbing Your Power: Superuser Access**

While you are logged in as the user named `root`, you are referred to as *Superuser or administrator* and have extraordinary privileges. You can read from or write to any file on the system, execute programs that ordinary users cannot, and more. On a multiuser system you may not be permitted to know the `root` password, but someone—usually the *system administrator*—knows the `root` password and maintains the system. When you are running Linux on your own computer, you will assign a password to `root` when you install Linux.

**caution: Do not experiment as Superuser**

Feel free to experiment when you are logged in as yourself. When you log in as Superuser, also called `root` or administrator, or whenever you give the Superuser password, do only what you have to do and make sure you know exactly what you are doing. After you have completed the task at hand, revert to working as yourself. When working as Superuser you can damage the Linux system to such an extent that you will need to reinstall Linux to get it working again.
Getting the Facts: Where to Find Documentation

Distributions of Linux typically do not come with hardcopy reference manuals. However, its online documentation has always been one of Linux’s strengths. The manual (or man) and info pages have been available via the man and info utilities since early releases of the operating system. With the growth of Linux and the Internet, the sources of documentation have expanded. The following sections discuss some of the places you can look for information on various aspects of Linux.

The help Option

Most GNU utilities have a help option that displays information about the utility.

$ cat --help

Usage: cat [OPTION] [FILE]...

Concatenate FILE(s), or standard input, to standard output.

-A, --show-all                     equivalent to -vET
-b, --number-nonblank             number nonblank output lines
-e                                 equivalent to -vE
-E, --show-ends                    display $ at end of each line

...

If the information that help displays runs off the screen, send the output through the less pager (page 31) using a pipe:

$ ls --help | less

More information about pipes appears on page 52. Non-GNU utilities may use a h or help option to display help information.

Figure 2-1. The man utility displaying information about who

<table>
<thead>
<tr>
<th>WHO(1)</th>
<th>User Commands</th>
<th>WHO(1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>who - show who is logged on</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
SYNOPSIS

who [OPTION]... [ FILE | ARG1 ARG2 ]

DESCRIPTION

-a, --all
   same as -b -d --login -p -r -t -T -u
-b, --boot
   time of last system boot
-d, --dead
   print dead processes
-H, --heading
   print line of column headings
-i, --idle
   add idle time as HOURS:MINUTES, . or old (deprecated, use -u)

man: Displays the System Manual

The man (manual) utility displays pages (man pages) from the system documentation. This documentation is helpful when you know which utility you want to use but have forgotten exactly how to use it. You can also refer to the man pages to get more information about specific topics or to determine which features are available with Linux. Because the descriptions in the system documentation are often terse, they are most helpful if you already understand basically what a utility does.

To find out more about a utility, including the man utility itself, give the command man, followed by the name of the utility. Figure 2-1 shows the output of a man who command.

less (pager)

The command man man displays information about the man utility. The man utility automatically sends the output through a pager, usually less (page 45), which allows you to view a file one screen at a time. When you display a manual page in this manner, less displays a prompt (:) at the bottom of the screen after each screen of text and waits for you to request another screen by pressing the SPACE bar. Pressing h (help) displays a list of less commands. Pressing q (quit) stops man and causes the shell to display a prompt. You can search for topics covered by man pages by using the apropos utility (page 62).

Manual sections

Based on the FHS (Filesystem Hierarchy Standard, page 86), the Linux system manual and the man pages are
divided into ten sections. Each section describes related tools:

1. User Commands
2. System Calls
3. Subroutines
4. Devices
5. File Formats
6. Games
7. Miscellaneous
8. System Administration
9. Local
10. New

This layout closely mimics the way the set of UNIX manuals has always been divided. Unless you specify a manual section, `man` displays the earliest occurrence in the manual of the word you provide on the command line. Most users find the information they need in sections 1, 6, and 7; programmers and system administrators frequently need to consult the other sections.

In some cases the manual contains entries for different tools with the same name. For example, the following command displays the manual page for the `write` utility (page 67) from section 1 of the system manual:

```
$ man write
```

To see the manual page for the `write` system call from section 2, enter

```
$ man 2 write
```

The preceding command instructs `man` to look only in section 2 for the manual page. Use the `a` option (see the adjacent tip) to view all the `man` pages for a given subject (press `q` to move to the next section). Use `man a write` to view all the `man` pages for `write`.

**tip: Options**

An option modifies the way a utility or command works. Options are specified as one or more letters that are preceded by one or two hyphens (with some exceptions). The option appears following the name of the utility you are calling and a SPACE. Any other *arguments* (861) to the command follow the option and a SPACE. For more information refer to "Options" on page 109.

**tip: man and info display different information**
The **info** utility displays more complete and up-to-date information on GNU utilities than does **man**. When a **man** page displays abbreviated information on a utility that is covered by **info**, the **man** page refers you to **info**. The **man** utility frequently displays the only information available on non-GNU utilities. When **info** displays information on non-GNU utilities, it is frequently a copy of the **man** page.

**info: Displays Information About Utilities**

The character-based **info** utility is a menu-based hypertext system developed by the GNU project and distributed with Linux. The **info** utility includes a tutorial on itself (give the command **info info** or go to [www.gnu.org/software/texinfo/manual/info](http://www.gnu.org/software/texinfo/manual/info)) and documentation on many Linux shells, utilities, and programs developed by the GNU project (page 2). **Figure 2-2** shows the screen that **info** displays when you give the command **info**.

**Figure 2-2. The first screen that info displays**

Because the information on this screen is drawn from an editable file, your display may differ. When you see the initial **info** screen, you can press

- **h** to go through an interactive tutorial on **info**
- **?** to list **info** commands
- **SPACE** to scroll through the menu of items for which information is available
• m followed by the name of the menu item you want to display

• q to quit

The notation info uses to describe keyboard keys may not be familiar to you. The notation C-h is the same as CONTROL-H. Similarly M-x means hold down the META or ALT key and press x. (On some systems you need to press ESCAPE and then x to duplicate the function of META-x.)

After giving the command info, press the SPACE bar a few times to scroll the display. Figure 2-3 shows the entry for sleep. The asterisk at the left end of the line means that this entry is the beginning of a menu item. Following the asterisk is the name of the menu item, followed by a colon, the name of the package (in parentheses) that the menu item belongs to, other information, and a description of the item on the right.

Figure 2-3. The screen that info displays after you press SPACE a few times

[View full size image]

Each menu item is an active link to the info page that describes the item. To jump to that page, move the cursor to the line containing the menu item and press RETURN. Alternatively you can type the name of the menu item in a menu command to view the information. To get information on sleep, for example, you give the command m sleep, followed by a RETURN. When you type m (for menu), the cursor moves to the bottom line of the screen and displays Menu item: Typing sleep displays sleep on that line, and pressing RETURN takes you to the menu item you have chosen.

Figure 2-4 shows the top node of information on sleep. A node is one group of information that you can scroll through with the SPACE bar. To get to the next node, press n. Press p to get to the previous node. You can always press d to display the initial menu (Figure 2-2).
As you read this book and learn about new utilities, you can use `man` or `info` to find out more about the utilities. If you can print PostScript documents, you can print a manual page with the `man` utility using the `-t` option (for example, `man -t cat | lpr` prints information about the `cat` utility). Better yet, use a browser to look at the documentation at [www.tldp.org](http://www.tldp.org) and print the information from the browser.

**HOWTOs: Finding Out How Things Work**

A HOWTO document explains in detail how to do something related to Linux—from setting up a specialized piece of hardware to performing a system administration task to setting up specific networking software. Mini-HOWTOs offer shorter explanations. As with Linux software, one person or a few people generally are responsible for a HOWTO document, yet many people contribute to it.

The Linux Documentation Project (LDP, page 35) site houses most HOWTO and mini-HOWTO documents. Use a browser to go to [www.tldp.org](http://www.tldp.org), click **HOWTOs**, and pick the index you want to use to find a HOWTO or mini-HOWTO. Or use the LDP search feature on its home page to find HOWTOs and more.

**Using the Internet to Get Help**

The Internet provides many helpful sites related to Linux. Aside from sites that carry various forms of documentation, you can enter an error message that you are having a problem with in a search engine such as Google ([www.google.com](http://www.google.com)). Enclose the error message within double quotation marks to improve the quality of your results. You will likely find a post concerning your problem and how to solve it. See Figure 2-5.
GNU

GNU makes many of its manuals available at www.gnu.org/manual. In addition, go to the GNU home page (www.gnu.org) for more documentation and other GNU resources. Many of the GNU pages and resources are available in a wide variety of languages.

The Linux Documentation Project

The Linux Documentation Project (www.tldp.org), which has been around for almost as long as Linux, houses a complete collection of guides, HOWTOs, FAQs, man pages, and Linux magazines. The home page is available in English, Portuguese, Spanish, Italian, Korean, and French and is easy to use, supporting local text searches. It also has a complete set of links (Figure 2-6) that can help you find almost anything you want that is related to Linux (click Links in the Search box or go to www.tldp.org/links). The links page includes sections on general information, events, getting started, user groups, mailing lists, and newsgroups, each containing many subsections.

More About Logging In

This section covers what to do if you have a problem logging in, how to use virtual consoles, how to log in remotely, and how to change your password.

What to Do If You Cannot Log In

When you enter your username or password incorrectly, the system displays an error message after you enter both your username and your password. This message indicates that you have entered either the login name or the password incorrectly or that they are not valid. It does not differentiate between an unacceptable login name and an unacceptable password to discourage unauthorized people from guessing names and passwords to gain access to the system. Some common reasons that logins fail are listed here:

- **Log In on the Right Machine**
  
The login/password combination may not be valid if you are trying to log in on the wrong machine. On a larger, networked system, you may have to specify the machine that you want to connect to before you can log in.

- **Login Name and Password Are Case Sensitive**
  
Make sure the CAPS LOCK key is off and that you enter your name and password exactly as specified or as you set them up.

- **Make Sure Your Login Name Is Valid**
  
The login/password combination may not be valid if you have not been set up as a user.

Refer to "Changing Your Password" on page 37 when you want to change your password.

Logging Out

To log out from a character-based interface, press CONTROL-D or give the command `exit` in response to the shell prompt.

Using Virtual Consoles

When running Linux on a personal computer, you frequently work with the display and keyboard attached to the computer. Using this physical console, you can access as many as 63 virtual consoles (also called virtual terminals). Some are set up to allow logins, whereas others act as graphical displays. To switch between virtual consoles, hold down the CONTROL and ALT keys and press the function key that corresponds to the console you want to view. For example, CONTROL-ALT-F5 displays the fifth virtual console. This book refers to the console that you see when you first boot a system (or press CONTROL-ALT-F1) as the system console (or just console).

Typically, six virtual consoles are active and have text login sessions running. When you want to use both a character-based interface and a GUI, you can set up a character-based session on one virtual console and a graphical session on another. Whichever virtual console you start a graphical session from, the graphical session finds the first unused virtual console (typically number seven).

Changing Your Password
If someone else assigned you a password, it is a good idea to give yourself a new one. A good password is seven or eight characters long and contains a combination of numbers, uppercase and lowercase letters, and punctuation characters. Avoid using control characters (such as CONTROL-H) because they may have a special meaning to the system, making it impossible for you to log in. Do not use names, words from English or other languages, or other familiar words that someone can easily guess.

For security reasons none of the passwords you enter is ever displayed by any utility.

**security: Protect your password**

Do not allow someone to find out your password: Do not put your password in a file that is not encrypted, allow someone to watch you type your password, give it to someone you do not know (a system administrator never needs to know your password), or write it down.

**security: Choose a password that is difficult to guess**

Do not use phone numbers, names of pets or kids, birthdays, words from a dictionary (not even a foreign language), and so forth. Do not use permutations of these items.

**security: Differentiate between important and less important passwords**

It is important to differentiate between important and less important passwords. For example, Web site passwords for blogs or download access are not very important; it is not bad if you choose the same password for these types of sites. However, your login, mail server, and bank account Web site passwords are critical: Never use these passwords for an unimportant Web site.

To change your password, give the command `passwd` from a command line:

```
$ passwd
Changing password for user zach.
Changing password for zach
(current) UNIX password:
New UNIX password:
Retype new UNIX password:
passwd: all authentication tokens updated successfully.
```

The first item the system asks you for is your current (old) password. This password is verified to ensure that an unauthorized user is not trying to alter your password. Next the system requests the new password.

A password should meet the following criteria to be relatively secure. Only the first item is mandatory.

- It must be at least six characters long (or longer if the system administrator sets it up that way).
- It should not be a word in a dictionary of any language, no matter how seemingly obscure.
- It should not be the name of a person, place, pet, or other thing that might be discovered easily.
• It should contain at least two letters and one digit.

• It should not be your login name, the reverse of your login name, or your login name shifted by one or more characters.

• If you are changing your password, the new password should differ from the old one by at least three characters. Changing the case of a character does not make it count as a different character.

After you enter your new password, the system asks you to retype it to make sure you did not make a mistake when you entered it the first time. If the new password is the same both times you enter it, your password is changed. If the passwords differ, it means that you made an error in one of them, and the system displays an error message:

Sorry, passwords do not match

If your password is not long enough, the system displays the following message:

BAD PASSWORD: it is too short

When it is too simple, the system displays this message:

BAD PASSWORD: it is too simplistic/systematic

When it is formed from words, the system displays this message:

BAD PASSWORD: it is based on a dictionary word

If you get one of these messages you need to start over. Press RETURN a few times until the shell displays a prompt and run passwd again.

When you successfully change your password, you change the way you log in. If you forget your password, Superuser can change it and tell you your new password.
Chapter Summary

As with many operating systems, your access to a Linux system is authorized when you log in. You enter your username in response to the **login** prompt, followed by a password. You can change your password any time while you are logged in. Choose a password that is difficult to guess and that conforms to the criteria imposed by the utility that changes your password.

The system administrator is responsible for maintaining the system. On a single-user system, you are the system administrator. On a small, multiuser system, you or another user act as the system administrator, or this job may be shared. On a large, multiuser system or network of systems, there is frequently a full-time system administrator. When extra privileges are required to perform certain system tasks, the system administrator logs in as the **root** user by entering the username **root** and the **root** password; this user is called Superuser or administrator. On a multiuser system, several trusted users may be given the **root** password.

Do not work as Superuser as a matter of course. When you have to do something that requires Superuser privileges, work as Superuser for only as long as you need to; then revert to working as yourself as soon as possible.

The **man** utility provides online documentation on system utilities. This utility is helpful both to new Linux users and to experienced users who must often delve into the system documentation for information on the fine points of a utility's behavior. The **info** utility helps the beginner and the expert alike. It includes a tutorial on its use and documentation on many Linux utilities.
Exercises

1. The following message is displayed when you attempt to log in with an incorrect username or an incorrect password:

   Login incorrect

   This message does not indicate whether your username, your password, or both are invalid. Why does it not tell you this information?

2. Give three examples of poor password choices. What is wrong with each? Include one that is too short. Give the error message the system displays.

3. Is fido an acceptable password? Give several reasons why or why not.

4. What would you do if you could not log in?

5. Try to change your password to dog. What happens? Change it to a more secure password. What makes that password relatively secure?
Advanced Exercises

6. Change your login shell to **tcsh** without becoming **root** (Superuser).

7. How many **man** pages are in the **Devices** subsection of the system manual? *(Hint: **Devices** is a subsection of **Special Files**.)*

8. The example on page 31 shows that **man** pages for **write** appear in sections 1 and 2 of the system manual. Explain how you can use **man** to determine which sections of the system manual contain a manual page with a given name.

9. How would you find out which Linux utilities create and work with archive files?
Chapter 3. Command Line Utilities

IN THIS CHAPTER

less Is more: Displaying a Text File One Screen at a Time 45

Working with Files 45

lpr: Prints a File 47

| (Pipe): Communicates Between Processes 52

Compressing and Archiving Files 56

Obtaining User and System Information 63

When Linus Torvalds introduced Linux and for a long time thereafter, Linux did not have a graphical user interface: It ran on character-based terminals only. All the tools ran from a command line. Today the Linux GUI is important, but many people—especially system administrators—run many command line programs. Command line utilities are often faster, more powerful, or more complete than their GUI counterparts. Sometimes there is no GUI counterpart to a text-based utility; some people just prefer the hands-on feeling of the command line.

When you work with a command line interface, you are working with a shell. Before you start working with a shell, it is important to understand something about the characters that are special to the shell, so this chapter starts with a discussion of shell special characters. The chapter then describes four basic utilities you can use to create and manipulate files (ls, cat, rm, and less) and one utility that tells you the name of the system you are using (hostname). It continues with a section on additional file manipulation utilities (including lpr, which prints files), followed by a brief discussion of how you can use a pipe on the command line. This chapter then describes utilities that compress and decompress files, locate other utilities, obtain user and system information, and allow you to communicate with other users. It concludes with a section on email.

**tip: Run these utilities from a command line**

This chapter describes command line (i.e., text-based) utilities. You can experiment with these utilities from a terminal, a terminal emulator within a GUI, or a virtual console (page 36).
Special Characters

Special characters, which have a special meaning to the shell, are discussed in "Filename Generation/Pathname Expansion" on page 127. These characters are mentioned here so that you can avoid accidentally using them as regular characters until you understand how the shell interprets them. For example, it is best to avoid using any of the following characters in a filename (even though emacs and some other programs do) because they make the file harder to reference on the command line:

\& ; | * ? ' " ' [ ] ( ) $ < > { } ^ # / \ % ! ~ +

Whitespace

Although not considered special characters, RETURN, SPACE, and TAB also have special meanings to the shell. RETURN usually ends a command line and initiates execution of a command. The SPACE and TAB characters separate elements on the command line and are collectively known as whitespace or blanks.

If you need to use one of the characters that has a special meaning to the shell as a regular character, you can quote (or escape) it. When you quote a special character, you keep the shell from giving it special meaning. The shell treats a quoted special character as a regular character.

Backslash

To quote a character, precede it with a backslash (\). When you have two or more special characters together, you must precede each with a backslash (for example, enter ** as \*\* ). You can quote a backslash just as you would quote any other special character! by preceding it with a backslash (\).

Single quotation marks

Another way of quoting special characters is to enclose them between single quotation marks: ' ** '. You can quote many special and regular characters between a pair of single quotation marks: "This is a special character: >". The regular characters remain regular, and the shell also interprets the special characters as regular characters.

The only way to quote the erase character (CONTROL-H), the line kill character (CONTROL-U), and other control characters (try CONTROL-M) is by preceding it with a CONTROL-V. Single quotation marks and backslashes do not work. Try the following:

$ echo 'xxxxxxCONTROL-U'

$ echo xxxxxxxCONTROL-V CONTROL-U
optional

Although you cannot see the CONTROL-U displayed by the second of the preceding pair of commands, it is there. The following command sends the output of `echo` (page 647) through a pipe (page 52) to `od` (page 737) to display the CONTROL-U as an octal 25 (025):

```
$ echo xxxxxxCONTROL-V CONTROL-U | od -c
 0000000   x   x   x   x   x   x 025  
 0000010
```

The `\n` is the NEWLINE character that `echo` sends at the end of its output.
Basic Utilities

One of the important advantages of Linux is that it comes with thousands of utilities that perform myriad functions. You will use utilities whenever you use Linux, whether you use them directly by name from the command line or indirectly from a menu or icon. The following sections discuss some of the most basic and important utilities; these utilities are available from a character-based interface. Some of the more important utilities are also available from a GUI, and some are available only from a GUI.

The term *directory* is used extensively in the next sections. A directory is a resource that can hold files. On other operating systems, including Windows, Macintosh, and frequently Linux GUIs, a directory is referred to as a folder. That is a good analogy: A directory is a folder that can hold files.

**tip: In this chapter you work in your home directory**

When you log in on the system, you are working in your *home directory*. In this chapter that is the only directory you use: All the files you create in this chapter are in your home directory. Chapter 4 goes into more detail about directories.

**ls: Lists the Names of Files**

Using the editor of your choice, create a small file named *practice*. (A tutorial on *vim* appears on page 141 and a tutorial on *emacs* appears on page 198.) After exiting from the editor, you can use the *ls* (list) utility to display a list of the names of the files in your home directory. In the first command in Figure 3-1 *ls* lists the name of the *practice* file. (You may also see files the system or a program created automatically.) Subsequent commands in Figure 3-1 display the contents of the file and remove the file. These commands are described next.

**Figure 3-1. Using ls, cat, and rm on the file named practice**

```
$ ls
practice

$ cat practice
This is a small file that I created
with a text editor.

$ rm practice
$ ls

$ cat practice
cat: practice: No such file or directory

$ 
```

**cat: Displays a Text File**
The `cat` utility displays the contents of a text file. The name of the command is derived from `catenate`, which means to join together, one after the other. (Figure 5-8 on page 118 shows how to use `cat` to string together the contents of three files.)

A convenient way to display the contents of a file to the screen is by giving the command `cat`, followed by a SPACE and the name of a file. Figure 3-1 shows `cat` displaying the contents of `practice`. This figure shows the difference between the `ls` and `cat` utilities: The `ls` utility displays the name of a file, whereas `cat` displays the contents of a file.

**rm: Deletes a File**

The `rm` (remove) utility deletes a file. Figure 3-1 shows `rm` deleting the file named `practice`. After `rm` deletes the file, `ls` and `cat` show that `practice` is no longer in the directory. The `ls` utility does not list its filename, and `cat` says that there is no such file. Use `rm` carefully.

**tip: A safer way of removing files**

You can use the interactive form of `rm` to make sure that you delete only the file(s) you intend to delete. When you follow `rm` with the `-i` option (see page 31 for a tip on options) and the name of the file you want to delete, `rm` displays the name of the file and then waits for you to respond with `y` (yes) before it deletes the file. It does not delete the file if you respond with a string that does not begin with `y`.

```
$ rm -i toollist
rm: remove regular file 'toollist'? y
```

**Optional:** You can create an alias (page 312) and put it in your startup file (page 83) so that `rm` always runs in interactive mode.

**less Is more: Displaying a Text File One Screen at a Time**

**Pagers**

When you want to view a file that is longer than one screen, you can use either the `less` utility or the `more` utility. Each of these utilities pauses after displaying a screen of text. Because these utilities show one page at a time, they are called **pagers**. Although they are very similar, they have subtle differences. At the end of the file, for example, `less` displays an **EOF** (end of file) message and waits for you to press **q** before returning you to the shell. In contrast, `more` returns you directly to the shell. In both utilities you can press **h** to display a help screen that lists commands you can use while paging through a file. Replace the `cat` command in Figure 3-1 with `less practice` and `more practice` to see how these commands work. Use the command `less /etc/termcap` if you want to experiment with a long file. Refer to page 697 for more information on `less`.

**tip: Filename completion**

After you enter one or more letters of a filename (following a command) on a command line, press **TAB** and the shell will complete as much of the filename as it can. When only one filename starts with the characters you entered, the shell completes the filename and places a SPACE after it. You can keep...
typing or you can press RETURN to execute the command at this point. When the characters you entered do not uniquely identify a filename, the shell completes what it can and waits for more input. When pressing TAB does not change the display, press TAB again to display a list of possible completions. (Refer to "Pathname Completion" on page 308.)

The preceding description assumes you are running bash. Filename completion works a little differently if you are running tcsh; see "Word Completion" on page 350.

hostname: Displays the System Name

The hostname command displays the name of the system you are working on. Use this command if you are not sure that you are logged in on the right system.

$ hostname
bravo.example.com
Working with Files

The following sections describe utilities that copy, move, and print files.

**cp: Copies a File**

The cp (copy) utility (Figure 3-2) makes a copy of a file. This utility can copy any file, including text and executable program (binary) files. You can use cp to make a backup copy of a file or a copy to experiment with.

The cp command line uses the following syntax to specify source and destination files:

```
cp source-file destination-file
```

The `source-file` is the name of the file that `cp` will copy. The `destination-file` is the name that `cp` assigns to the resulting (new) copy of the file.

**caution: cp can destroy a file**

If the `destination-file` exists before you give a `cp` command, `cp` overwrites it. Because `cp` overwrites (and destroys the contents of) an existing `destination-file` without warning, take care not to cause `cp` to overwrite a file that you need. The `cp -i` (interactive) option (see page 31 for a tip on options) prompts you before it overwrites a file.

The following example assumes that the file named `orange.2` exists before you give the `cp` command. The user answers `y` to overwrite the file:

```
$ cp -i orange orange.2
```

The `cp` command line in Figure 3-2 copies the file named `memo` to `memo.copy`. The period is part of the filename; just another character. The initial `ls` command shows that `memo` is the only file in the directory. After the `cp` command, a second `ls` shows two files in the directory, `memo` and `memo.copy`.

Sometimes it is useful to incorporate the date in the name of a copy of a file. The following example includes the date January 30 (0130) in the copied file:

```
$ cp memo memo.0130
```

Although it has no significance to Linux, the date can help you find a version of a file that you created on a certain date. It can also help you avoid overwriting existing files by providing a unique filename each day. Refer to "Filenames" on page 78.

Use `scp` (page 758) or `ftp` (page 671) when you need to copy a file from one system to another on a common network.
**mv: Changes the Name of a File**

The `mv` (move) utility can rename a file without making a copy of it. The `mv` command line specifies an existing file and a new filename using the same syntax as `cp`:

```
mv existing-filename new-filename
```

Figure 3-2. `cp` copies a file

```
$ ls
memo
$ cp memo memo.copy
$ ls
memo memo.copy
```

Figure 3-3. `mv` renames a file

```
$ ls
memo
$ mv memo memo.0130
$ ls
memo.0130
```

The command line in Figure 3-3 changes the name of the file `memo` to `memo.0130`. The initial `ls` command shows that `memo` is the only file in the directory. After you give the `mv` command, `memo.0130` is the only file in the directory. Compare this result to that of the earlier `cp` example.

The `mv` utility can be used for more than changing the name of a file. Refer to "mv, cp: Moves or Copies a File" on page 90.

**caution: mv can destroy a file**

Just as `cp` can destroy a file, so can `mv`. Also like `cp`, `mv` has a `i` (interactive) option. See the caution box labeled "`cp` can destroy a file" on page 46.

**lpr: Prints a File**
The `lpr` (line printer) utility places one or more files in a print queue for printing. Linux provides print queues so that only one job is printed on a given printer at a time. A queue allows several people or jobs to send output simultaneously to a single printer with the expected results. On machines with access to more than one printer, you can use the `-P` option to instruct `lpr` to place the file in the queue for a specific printer, including one that is connected to another machine on the network. The following command prints the file named `report`:

```
$ lpr report
```

Because this command does not specify a printer, the output goes to the default printer, which is the printer when you have only one printer.

The next command line prints the same file on the printer named `mailroom`:

```
$ lpr -Pmailroom report
```

You can see what jobs are in the print queue by using the `lpq` utility:

```
$ lpq
lp is ready and printing

Rank   Owner Job Files Total Size
active alex 86 (standard input) 954061 bytes
```

In this example, Alex has one job that is being printed; no other jobs are in the queue. You can use the job number (86 in this case) with the `lprm` utility to remove the job from the print queue and stop it from printing:

```
$ lprm 86
```

You can send more than one file to the printer with a single command. The following command line prints three files on the printer named `laser1`:

```
$ lpr -Plaser1 05.txt 108.txt 12.txt
```

**grep: Finds a String**

The `grep` (global regular expression print) utility searches through one or more files to see whether any contain a specified string of characters. It does not change the file it searches but simply displays each line that contains the string.

```
[1] Originally this utility's name was a play on an ed\lan original UNIX editor, available on Linux\command:\n```
Originally this utility's name was a play on an edan original UNIX editor, available on Linux command:

```
g/re/p
```

In this command the `g` stands for global, `re` is a regular expression delimited by slashes, and `p` means print.

The `grep` command in Figure 3-4 searches through the file `memo` for lines that contain the string `credit` and displays a single line that meets this criterion. If `memo` contained such words as `discredit`, `creditor`, or `accreditation`, `grep` would have displayed those lines as well because they contain the string it was searching for. The `w` option causes `grep` to match only whole words. You do not need to enclose the string you are searching for in single quotation marks, but doing so allows you to put SPACEs and special characters in the search string.

The `grep` utility can do much more than search for a simple string in a single file. Refer to page 683 for more information on `grep`.

Figure 3-4. `grep` searches for a string

```
$ cat memo

Helen:

In our meeting on June 6 we discussed the issue of credit.

Have you had any further thoughts about it?

Alex

$ grep 'credit' memo

discussed the issue of credit.
```

**head:** Displays the Beginning of a File

By default the `head` utility displays the first ten lines of a file. You can use `head` to help you remember what a particular file contains. For example, if you have a file named `months` that lists the 12 months of the year in order, one to a line, `head` displays Jan through Oct (Figure 3-5).

This utility can display any number of lines, so you can use it to look at only the first line of a file, at a full screen, or even more. To specify the number of lines `head` displays, include a hyphen followed by the number of lines in the `head` command. For example, the following command displays only the first line of `months`:
The `head` utility can also display parts of a file based on a count of blocks or characters rather than lines. Refer to page 691 for more information on `head`.

**tail: Displays the End of a File**

The `tail` utility is similar to `head` but by default displays the last ten lines of a file. Depending on how you invoke it, this utility can display fewer or more than ten lines, use a count of blocks or characters rather than lines to display parts of a file, and display lines being added to a file that is changing. The following command causes `tail` to display the last five lines, Aug through Dec, of the `months` file shown in Figure 3-5:

```
$ cat months
Jan
Feb
Mar
Apr
May
Jun
Jul
Aug
Sep
Oct
Nov
Dec
```

```
$ head months
Jan
Feb
```
Figure 3-6. `sort` displays a file in order

```
$ cat days
Monday
Tuesday
Wednesday
Thursday
Friday
Saturday
Sunday
$ sort days
Friday
Monday
Saturday
Sunday
Thursday
Tuesday
Wednesday
```
$ tail -5 months

Aug
Sep
Oct
Nov
Dec

You can monitor lines as they are added to the end of the growing file named `logfile` with the following command:

$ tail -f logfile

Press the interrupt key (usually CONTROL-C) to stop tail and display the shell prompt. Refer to page 783 for more information on tail.

**sort: Displays a File in Order**

The `sort` utility displays the contents of a file in order by lines but does not change the original file. If you have a file named `days` that contains the name of each day of the week in order on a separate line, `sort` displays the file in alphabetical order (Figure 3-6).

The `sort` utility is useful for putting lists in order. The `u` option generates a sorted list in which each line is unique (no duplicates). The `n` option puts a list of numbers in order. Refer to page 762 for more information on sort.

![Figure 3-7. uniq removes duplicate lines](image)

$ cat dups

Cathy
Fred
Joe
John
Mary
Mary
Paula
uniq: Removes Duplicate Lines from a File

The `uniq` (unique) utility displays a file, skipping adjacent duplicate lines, but does not change the original file. If a file contains a list of names and has two successive entries for the same person, `uniq` skips the extra line (Figure 3-7).

If a file is sorted before it is processed by `uniq`, this utility ensures that no two lines in the file are the same. (Of course, `sort` can do that all by itself with the `-u` option.) Refer to page 812 for more information on `uniq`.

diff: Compares Two Files

The `diff` (difference) utility compares two files and displays a list of the differences between them. This utility does not change either file, so it is useful when you want to compare two versions of a letter or a report or two versions of the source code for a program.

The `diff` utility with the `-u` (unified output format) option first displays two lines indicating which of the files you are comparing will be denoted by a plus sign (+) and which by a minus sign (−). In Figure 3-8, a minus sign indicates the `colors.1` file; a plus sign indicates the `colors.2` file.

The `diff` command breaks long, multiline text into hunks. Each hunk is preceded by a line starting and ending with two at signs (@@). This hunk identifier indicates the starting line number and the number of lines from each file for this hunk. In Figure 3-8, the @@ indicates that the hunk covers the section of the `colors.1` file (indicated by a minus sign) from the first line and continuing for six lines (for a total of seven lines). Similarly the +1,5 indicates that the hunk covers `colors.2` from the first line through five subsequent lines.

Figure 3-8. `diff` displaying the unified output format

$ diff -u colors.1 colors.2

--- colors.1 Fri Nov 25 15:45:32 2005
+++ colors.2 Fri Nov 25 15:24:46 2005
@@ -1,6 +1,5 @@

red
+blue
green
yellow
-pink
-purple
orange

Following these header lines, `diff` displays each line of text with a leading minus sign, plus sign, or nothing. The leading minus sign indicates that the line occurs only in the file denoted by the minus sign. The leading plus sign indicates that the line comes from the file denoted by the plus sign. A line that begins with neither a plus sign nor a minus sign occurs in both files in the same location. Refer to page 638 for more information on `diff`.

**file: Tests the Contents of a File**

You can use the `file` utility to learn about the contents of any file on a Linux system without having to open and examine the file yourself. In the following example, `file` reports that `letter_e.bz2` contains data that was compressed by the `bzip2` utility (page 56):

```
$ file letter_e.bz2
letter_e.bz2: bzip2 compressed data, block size = 900k
```

Next `file` reports on two more files:

```
$ file memo zach.jpg
memo: ASCII text
zach.jpg: JPEG image data, ... resolution (DPI), 72 x 72
```

Refer to page 653 for more information on `file`.
(Pipe): Communicates Between Processes

Because pipes are integral to the functioning of a Linux system, they are introduced here for use in examples. Pipes are covered in detail on page 122.

A process is the execution of a command by Linux (page 292). Communication between processes is one of the hallmarks of UNIX/Linux. A pipe (written as a vertical bar, |, on the command line and appearing as a solid or broken vertical line on keyboards) provides the simplest form of this kind of communication. Simply put, a pipe takes the output of one utility and sends that output as input to another utility. Using UNIX/Linux terminology, a pipe takes standard output of one process and redirects it to become standard input of another process. (See page 113 for more information on standard input and output.) Most of what a process displays on the screen is sent to standard output. If you do not redirect it, this output appears on the screen. Using a pipe, you can redirect the output so that it becomes instead standard input of another utility. A utility such as head can take its input from a file whose name you specify on the command line following the word head, or it can take its input from standard input. For example, you can give the command shown in Figure 3-5 on page 49 as follows:

$ cat months | head
Jan
Feb
Mar
Apr
May
Jun
Jul
Aug
Sep
Oct

The next command displays the first line of the months file:

$ cat months | head -1
Jan

You can use a pipe to send output of a program to the printer:

$ tail months | lpr
Four More Utilities

The `echo` and `date` utilities are two of the most frequently used from the large collection of Linux utilities. The `script` utility helps you record part of a session in a file, and `unix2dos` makes a copy of a text file that can be read on a Windows machine.

**echo: Displays Text**

The `echo` utility copies anything you put on the command line, after `echo`, to the screen. Some examples are shown in Figure 3-9. The last example shows what the shell does with an unquoted asterisk (`*`) on the command line: It expands the asterisk into a list of filenames in the directory.

![Figure 3-9. echo copies the command line (but not the word echo) to the screen](image)

```sh
$ ls
memo memo.0714 practice
$ echo Hi
Hi
$ echo This is a sentence.
This is a sentence.
$ echo star: *
star: memo memo.0714 practice
$ 
```

The `echo` utility is a good tool for learning about the shell and other Linux programs. Some examples on page 129 use `echo` to illustrate how special characters, such as the asterisk, work. Throughout the chapters explaining the shells, `echo` helps explain how shell variables work and how you can send messages from shell scripts to the screen. Refer to page 647 for more information on `echo`.

**date: Displays the Time and Date**

The `date` utility displays the current date and time:

```sh
$ date
Thu Jan 20 10:24:00 PST 2005
```

The following example shows how you can choose the format and select the contents of the output of `date`. Refer
The following example shows how you can choose the format and select the contents of the output of \texttt{date}. Refer to page 630 for more information on \texttt{date}.

\begin{verbatim}
$ date +"%A %B %d"
Thursday January 20
\end{verbatim}

\textbf{script: Records a Linux Session}

The \texttt{script} utility records all or part of a login session, including your input and the system's responses. This utility is useful only from character-based devices, such as a terminal or a terminal emulator. It does capture a session with \texttt{vim}; however, because \texttt{vim} uses control characters to position the cursor and display different typefaces, such as bold, the output will be difficult to read and may not be useful. When you \texttt{cat} a file that has captured a \texttt{vim} session, the session quickly passes before your eyes.

By default \texttt{script} captures the session in a file named \texttt{typescript}. To use a different filename, follow the \texttt{script} command with a SPACE and the new filename. To append to a file, use the \texttt{-a} option after \texttt{script} but before the filename; otherwise, \texttt{script} overwrites an existing file. Following is a session being recorded by \texttt{script}:

\begin{verbatim}
$ script
Script started, file is typescript
$ date
Thu Jan 20 10:28:56 PST 2005

$ who am i
alex pts/4 Jan 8 22:15
$

$ apropos mtools
mtools (1) - utilities to access DOS disks in Unix
mtools.conf [mtools] (5) - mtools configuration files
mtoolstest (1) - tests and displays the configuration

$ exit
Script done, file is typescript
$
\end{verbatim}
Use the `exit` command to terminate a script session. You can view the file you created with `cat`, `less`, `more`, or an editor. Following is the file that was created by the preceding `script` command:

```
$ cat typescript

Script started on Thu Jan 20 10:28:56 2005

$ date
Thu Jan 20 10:28:56 PST 2005

$ who am i
alex pts/4 Jan 8 22:15

$

$ apropos mtools

mtools (1) - utilities to access DOS disks in Unix
mtools.conf [mtools] (5) - mtools configuration files
mtoolstest (1) - tests and displays the configuration

$ exit

Script done on Thu Jan 20 10:29:58 2005

$

If you will be editing the file with `vim`, `emacs`, or another editor, you can use `dos2unix` to eliminate from the `typescript` file the `^M` characters that appear at the ends of the lines.

**unix2dos:** Converts Linux Files to Windows Format

If you want to share a text file that you created on a Linux system with someone on a Windows system, you need to convert the file before the person on the Windows system can read it easily. The `unix2dos` utility converts a Linux text file so that it can be read on a Windows system. Give the following command to convert a file named `memo.txt` (created with a text editor) to a DOS-format file:

```
$ unix2dos memo.txt
```

Without any options `unix2dos` overwrites the original file. You can now email the file as an attachment to someone on a Windows system.
You can use the `dos2unix` utility to convert DOS files so they can be read on a Linux system:

```
$ dos2unix memo.txt
```

See the `unix2dos` and `dos2unix man` pages for more information.

You can also use `TR` (page 804) to change a DOS text file into a Linux text file. In the following example, the `-d` option causes `TR` to remove RETURNS (represented by `\r`) as it makes a copy of the file:

```
$ cat memo | tr -d '\r' > memo.txt
```

Converting a file the other way without `unix2dos` is not as easy.
Compressing and Archiving Files

Large files use a lot of disk space and take longer than smaller files to transfer from one system to another over a network. If you do not need to look at the contents of a large file very often, you may want to save it on a CD, DVD, or other medium and remove it from the hard disk. If you have a continuing need for the file, retrieving a copy from a CD may be inconvenient. To reduce the amount of disk space you use without removing the file entirely, you can compress the file without losing any of the information it holds. Also you may frequently download compressed files from the Internet. The utilities described in this section compress and decompress files.

bzip2: Compresses a File

The bzip2 utility (sources.redhat.com/bzip2) compresses a file by analyzing it and recoding it more efficiently. The new version of the file looks completely different. In fact, because the new file contains many nonprinting characters, you cannot view it directly. The bzip2 utility works particularly well on files that contain a lot of repeated information, such as text and image data, although most image data is already in a compressed format.

The following example shows a boring file. Each of the 8,000 lines of this file, named letter_e, contains 72 e's and a NEWLINE character that marks the end of the line. The file occupies more than half a megabyte of disk storage.

```
$ ls -l
-rw-rw-r--  1 sam sam 584000 Mar  1 22:31 letter_e
```

The l (long) option causes ls to display more information about a file. Here it shows that letter_e is 584,000 bytes long. The v (verbose or v) option causes bzip2 to report how much it was able to reduce the size of the file. In this case, it shrank the file by 99.99 percent:

```
$ bzip2 -v letter_e
letter_e: 11680.00:1, 0.001 bits/byte, 99.99% saved, 584000 in, 50 out.
$ ls -l
-rw-rw-r--  1 sam sam 50 Mar  1 22:31 letter_e.bz2
```

.bz2 filename extension

Now the file is only 50 bytes long. The bzip2 utility also renamed the file, appending .bz2 to its name. This naming convention reminds you that the file is compressed; you would not want to display or print it, for example, without first decompressing it. The bzip2 utility does not change the modification date associated with the file, even though it completely changes the file's contents.

In the following, more realistic example, the file zach.jpg contains a computer graphics image:

```
$ ls -l
```

The `gzip` utility can reduce the size of the file by only 28 percent because the image is already in a compressed format:

```
$ bzip2 -v zach.jpg
zach.jpg:  1.391:1,  5.749 bits/byte, 28.13% saved, 33287 in, 23922 out.
```

Refer to page 596 and the `Bzip2 mini-HOWTO` (see page 34 for help finding it) for more information.

**bunzip2 and bzcat: Decompress a File**

You can use the `bunzip2` utility to restore a file that has been compressed with `bzip2`:

```
$ bunzip2 letter_e.bz2
$ ls -l
-rw-rw-r--  1 sam sam 584000 Mar  1 22:31 letter_e
$ bunzip2 zach.jpg.bz2
$ ls -l
-rw-r--r--  1 sam sam  33287 Mar  1 22:40 zach.jpg
```

The `bzcat` utility displays a file that has been compressed with `bzip2`. The equivalent of `cat` for `.bz2` files, `bzcat` decompresses the compressed data and displays the contents of the decompressed file. Like `cat`, `bzcat` does not change the source file. The pipe in the following example redirects the output of `zcat` so that instead of being displayed on the screen it becomes the input to `head`, which displays the first two lines of the file:

```
$ bzcat letter_e.bz2 | head -2
eeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeee
eeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeee
```

After `bzcat` is run, the contents of `letter_e.bz` is unchanged; the file is still stored on the disk in compressed form.
bzip2recover

The **bzip2recover** utility supports limited data recovery from media errors. Give the command `bzip2recover` followed by the name of the file from which you want to try to recover data.

**gzip: Compresses a File**

gunzip and zcat

The **gzip** (GNU zip) utility is older and less efficient than **bzip2**. Its flags and operation are very similar to those of **bzip2**. A file compressed by **gzip** is marked by a .gz filename extension. Linux stores manual pages in **gzip** format to save disk space; likewise, files you download from the Internet are frequently in **gzip** format. Use **gzip**, **gunzip**, and **zcat** just as you would use **bzip2**, **bunzip2**, and **bzcat**. Refer to page 688 for more information on **gzip**.

compress

The **compress** utility can also compress files, albeit not as well as **gzip**. This utility marks a file it has compressed by adding .Z to its name.

tip: gzip versus zip

Do not confuse **gzip** and **gunzip** with the **zip** and **unzip** utilities. These last two are used to pack and unpack zip archives containing several files compressed into a single file that has been imported from or is being exported to Windows. The **zip** utility constructs a zip archive, whereas **unzip** unpacks zip archives. The **zip** and **unzip** utilities are compatible with PKZIP, a Windows compress and archive program.

tar: Packs and Unpacks Files

The **tar** utility performs many functions. Its name is short for tape archive, as its original function was to create and read archive and backup tapes. Today it is used to create a single file (called a tar file) from multiple files or directory hierarchies and to extract files from a **tar** file.

In the following example, the first `ls` shows the existence and sizes of the files g, b, and d. Next `tar` uses `-c` (create), `-v` (verbose), and `-f` (write to or read from a file) options[^2] to create an archive named **all.tar** from these files. Each line of the output from **tar** starts with the letter a to indicate that it is appending to the archive. This letter is followed by the name of the file **tar** is appending.

[^2]: Although the original UNIX tar did not use a leading hyphen to indicate an option on the command line, it now accepts hyphens. The GNU tar described here will accept tar commands with or without a leading hyphen. This book uses the hyphen for consistency with most other utilities.

The **tar** utility does add overhead when it creates an archive. The next command shows that the archive file **all.tar** is about 9,700 bytes, whereas the sum of the sizes of the three files is about 6,000 bytes. This overhead is more appreciable on smaller files, such as the ones in this example.
$ ls -l g b d
-rw-r--r--  1 jenny jenny 1302 Aug 20 14:16 g
-rw-r--r--  1 jenny other 1178 Aug 20 14:16 b
-rw-r--r--  1 jenny jenny 3783 Aug 20 14:17 d

$ tar -cvf all.tar g b d
a g
a b
a d
$ ls -l all.tar
-rw-r--r--  1 jenny     jenny        9728 Aug 20 14:17 all.tar

$ tar -tvf all.tar
-rw-r--r--  jenny/jenny 1302 2003-08-20 14:16 2005 g
-rw-r--r--  jenny/other 1178 2003-08-20 14:16 2005 b
-rw-r--r--  jenny/jenny 3783 2003-08-20 14:17 2005 d

The final command in the preceding example uses the `t` option to display a table of contents for the archive. Use `x` instead of `t` to extract files from a `tar` archive. Omit the `v` option if you want `tar` to do its work silently.

You can use `bzip2`, `compress`, or `gzip` to compress `tar` files and make them easier to store and handle. Many files you download from the Internet are in one of these formats. Files that have been processed by `tar` and compressed by `bzip2` frequently have a filename extension of `.tar.bz2`. Those processed by `tar` and `gzip` have an extension of `.tz` or `.tar.gz`, while files processed by `tar` and `compress` use `.tar.Z` as the extension.

You can unpack a `tar`red and `gzip`ped file in two steps. (Follow the same procedure if the file was compressed by `bzip2`, but use `bunzip2` instead of `gunzip`.) The next example shows how to unpack the GNU `make` utility after it has been downloaded (`ftp.gnu.org/pub/gnu/make/make-3.80.tar.gz`):

$ ls -l mak*
-rw-rw-r--  1 sam sam 1211924 Jan 20 11:49 make-3.80.tar.gz

$ gunzip mak*
$ ls -l mak*
The first command lists the downloaded `tar` red and `gzip` ped file: `make-3.80.tar.gz` (about 1.2 megabytes). The asterisk (`*`) in the filename matches any characters in any filenames (page 129), so you end up with a list of files whose names begin with `mak`; in this case there is only one. Using an asterisk saves typing and can improve accuracy with long filenames. The `gunzip` command decompresses the file and yields `make-3.80.tar` (no `.gz` extension), which is about 4.8 megabytes. The `tar` command creates the `make-3.80` directory in the working directory and unpacks the files into it.

After `tar` exTRacts the files from the archive, the working directory contains two files whose names start with
mak: make-3.80.tar and make-3.80. The `d` (directory) option causes `ls` to display only file and directory names, not the contents of directories as it normally does. The final `ls` command shows the files and directories in the make-3.80 directory. Refer to page 786 for more information on `tar`.

**caution: tar: the `x` option may extract a lot of files**

Some `tar` archives contain many files. Run `tar` with the `-t` option and the name of the `tar` file to list the files in the archive without unpacking them. In some cases you may want to create a new directory (`mkdir` [page 80]), move the `tar` file into that directory, and expand it there. That way the unpacked files do not mingle with your existing files, and there is no confusion. This strategy also makes it easier to delete the extracted files. Some `tar` files automatically create a new directory and put the files into it. Refer to the preceding example.

**caution: tar: the `x` option can overwrite files**

The `x` option to `tar` overwrites a file that has the same filename as a file you are extracting. Follow the suggestion in the preceding caution box to avoid overwriting files.
optional

You can combine the `gunzip` and `tar` commands on one command line with a pipe (|), which redirects the output of `gunzip` so that it becomes the input to `tar`:

```
$ gunzip -c make-3.80.tar.gz | tar -xvf -
```

The `c` option causes `gunzip` to send its output through the pipe instead of creating a file. Refer to "Pipes" (page 122), `gzip` (page 688), and `tar` (page 786) for more information about how this command line works.

A simpler solution is to use the `z` option to `tar`. This option causes `tar` to call `gunzip` (or `gzip` when you are creating an archive) directly and simplifies the preceding command line to

```
$ tar -xvzf make-3.80.tar.gz
```

In a similar manner, the `j` option calls `bzip2` or `bunzip2`. 
Locating Commands

The `whereis` and `apropos` utilities help you find a command whose name you have forgotten or whose location you do not know. When there are multiple copies of a utility or program, `which` can tell you which copy you will run. The `slocate` utility searches for files on the local system.

**which and whereis: Locate a Utility**

When you give Linux a command, the shell searches a list of directories for a program with that name and runs the first one it finds. This list of directories is called a **search path**. For information on how to change the search path, refer to "PATH: Where the Shell Looks for Programs" on page 284. If you do not change the search path, the shell searches only a standard set of directories and then stops searching. Other directories on the system may also contain useful utilities, however.

**which**

The `which` utility locates utilities (commands) by displaying the full pathname to the file for the utility. (Chapter 4 contains more information on pathnames and the structure of the Linux filesystem.) The local system may include several commands that have the same name. When you type the name of a command, the shell searches for the command in your search path and runs the first one it finds. You can find out which copy of the program the shell will run by using `which`. In the following example, `which` reports the location of the `tar` command:

```
$ which tar
/bin/tar
```

The `which` utility can be helpful when a command seems to be working in unexpected ways. By running `which`, you may discover that you are running a nonstandard version of a tool or a different one than you expected. (Refer to "Important Standard Directories and Files" on page 86 for a list of standard locations for executable files.) For example, if `tar` is not working properly and you find that you are running `/usr/local/bin/tar` instead of `/bin/tar`, you might suspect that the local version is broken.

**whereis**

The `whereis` utility searches for files related to a utility by looking in standard locations instead of using your search path. For example, you can find the locations for files related to `tar`:

```
$ whereis tar
```

```
tar: /bin/tar /usr/include/tar.h /usr/share/man/man1/tar.1.gz
```

In this example `whereis` finds three references to `tar`: the `tar` utility file, a `tar` header file, and the `tar` man page.

**caution: which, whereis, and builtin commands**
Both the `which` and `whereis` utilities report only the names for commands as they are found on disk and do not report shell builtins (utilities that are built into a shell; see page 132). When you use `whereis` to try to find out where the `echo` command (which exists as both a utility program and a shell builtin) is kept, you get the following result:

```bash
$ whereis echo

echo: /bin/echo /usr/share/man/man1/echo.1.gz /usr/share/man/man1p/echo.1p.gz /usr/share/man/man3/echo.3x.gz
```

The `whereis` utility does not display the `echo` builtin. Even the `which` utility reports the wrong information:

```bash
$ which echo

/bin/echo
```

Under `bash` you can use the `type` builtin (page 487) to determine whether a command is a builtin.

```bash
$ type echo

echo is a shell builtin
```

**tip: which versus whereis**

Given the name of a program, `which` looks through the directories in your search path, in order, and locates the program. If more than one program with the specified name is in the search path, `which` displays the name of only the first one (the one you would run).

The `whereis` utility looks through a list of standard directories and works independently of your search path. Use `whereis` to locate a binary (executable) file, any manual pages, and source code for a program you specify; `whereis` displays all the files it finds.

**apropos: Searches for a Keyword**

When you do not know the name of the command you need to carry out a particular task, you can use a keyword and the `apropos` utility to search for it. (The `whatis` database has to be set up and regularly maintained with `makewhatis` for `apropos` to work; this task is typically handled by `cron`. Refer to `crontab` on page 624 for
more information.) This utility searches for the keyword in the short description line (the top line) of all of the man pages and displays those that contain a match. The man utility, when called with the \( \texttt{\texttt{\textbackslash}k} \) (keyword) option, displays the same output as apropos (it is actually the same command).

The following example shows the output of apropos when you call it with the who keyword. The output includes the name of each command, the section of the manual that contains it, and the brief description from the top of the man page. This list includes the utility that you need (who) and identifies other, related tools that you might find useful:

```bash
$ apropos who
at.allow [at] (5) - determine who can submit jobs via at or batch
at.deny [at] (5) - determine who can submit jobs via at or batch
jwhois (1) - client for the whois service
ldapwhoami (1) - LDAP who am i? tool
w (1) - Show who is logged on and what they are doing
who (1) - show who is logged on
whoami (1) - print effective userid

whatis
```

The whatis utility is similar to apropos but finds only complete word matches for the name of the utility.

```bash
$ whatis who
who (1) - show who is logged on

slocate: Searches for a File
```

The slocate utility, a secure version of locate, searches for files on the local system:

```bash
$ slocate motd
/lib/security/pam_motd.so
/usr/share/man/man5/motd.5.gz
/etc/motd
```
Before you can use `slocate` the `updatedb` utility must build/update the `slocate` database. Typically the database is updated once a day by a `cron` script. Refer to `crontab` on page 624 for more information.
Obtaining User and System Information

tip: If you are not on a network, skip the rest of this chapter

If you are the only user on a system that is not connected to a network, you may want to skip the rest of this chapter. If you are not on a network but are set up to send and receive email, read "Email" on page 69.

This section covers utilities that display who is using the system, what those users are doing, and how the system is running. To find out who is using the local system, you can employ several utilities that vary in the details they provide and the options they support. The oldest utility, who, produces a list of users who are logged in on the local system, the device each person is using, and the time the person logged in.

The w and finger utilities show more detail, such as each user's full name and the command line each user is running. You can use the finger utility to retrieve information about users on remote systems if your computer is attached to a network. Table 3-1 on page 67 summarizes the output of these utilities.

Figure 3-10. who lists who is logged in

$ who

who: Lists Users on the System

The who utility displays a list of users who are logged in. In Figure 3-10, the first column shows Alex and Jenny...
logged in. (Alex is logged in from two locations.) The second column shows the device that each person's terminal, workstation, or terminal emulator is connected to. The third column shows the date and time the person logged in.

The information that `who` displays is useful when you want to communicate with a user at your installation. When the user is logged in, you can use `write` (page 67) to establish communication immediately. If `who` does not list the user or if you do not need to communicate immediately, you can send email to that person (page 69).

If the output of `who` scrolls off the screen, you can redirect the output through a pipe so that it becomes the input to `less`, which displays the output one page at a time. You can also use a pipe to redirect the output through `grep` to look for a specific name.

If you need to find out which terminal you are using or what time you logged in, you can use the command `who am i`:

```
$ who am i
alex pts/5 Mar 27 12:33
```

### `finger`: Lists Users on the System

**security:** `finger` can be a security risk

On systems where security is a concern, the system administrator may disable `finger`. This utility can give information that can help a malicious user break into the system.

You can use `finger` to display a list of the users who are logged in on the system. In addition to login names, `finger` supplies each user's full name along with information about which device the person's terminal is connected to, how recently the user typed something on the keyboard, when the user logged in, and where the user is located (if the device appears in a system database). If the user has logged in over the network, the name of the remote system is shown as the user's location. For example, in Figure 3-11 `jenny` and `hls` are logged in from the remote system named `bravo`. The asterisk (*) in front of the name of Helen's device (TTY) indicates that she has blocked others from sending messages directly to her terminal (refer to "mesg: Denies or Accepts Messages" on page 68).

![Figure 3-11. `finger` lists who is logged in](image)

```
$ finger
Login     Name             Tty   Idle  Login Time   Office     Office Phone
root      root              1    1:35  May 24 08:38
alex      Alex Watson      /0          Jun  7 12:46 (:0)
alex      Alex Watson      /1      19  Jun  7 12:47 (:0)
jenny     Jenny Chen       /2    2:24  Jun  2 05:33 (bravo.example.com)
```
You can use `finger` to learn more about a particular individual by specifying that user on the command line. In Figure 3-12, `finger` displays detailed information about Alex. Alex is logged in and actively using one of his terminals (pts/1); he has not used his other terminal (pts/0) for 5 minutes and 52 seconds. You also learn from `finger` that if you want to set up a meeting with Alex, you should contact Jenny at extension 1693.

`.plan` and `.project`

Most of the information in Figure 3-12 was collected by `finger` from system files. The information shown after the heading `Plan:` however, was supplied by Alex. The `finger` utility searched for a file named `.plan` in Alex's home directory and displayed its contents. (Filenames that begin with a period, such as `.plan`, are not normally listed by `ls` and are called invisible filenames [page 80].) You may find it helpful to create a `.plan` file for yourself; it can contain any information you choose, such as your typical schedule, interests, phone number, or address. In a similar manner, `finger` displays the contents of the `.project` file in your home directory. If Alex had not been logged in, `finger` would have reported only his user information, the last time he logged in, the last time he read his email, and his plan.

Figure 3-12. `finger` II: lists details about one user

```bash
$ finger alex
Login: alex                        Name: Alex Watson
Directory: /home/alex              Shell: /bin/tcsh
On since Wed Jun  7 12:46 (PDT) on pts/0 from :0
      5 minutes 52 seconds idle
On since Wed Jun  7 12:47 (PDT) on pts/1 from bravo
Last login Wed Jun  7 12:47 (PDT) on 1 from bravo
New mail received Wed Jun  7 13:16 2006 (PDT)
      Unread since Fri May 26 15:32 2006 (PDT)
Plan:
I will be at a conference in Hawaii all next week. If you need to see me, contact Jenny

  Chen, x1693.
```

You can use `finger` to display a user's login name. For example, you might know that Helen's last name is Simpson but might not guess that her login name is `hls`. The `finger` utility, which is not case sensitive, can search for information on Helen using her first or last name. The following commands find the information you seek as
well as information on other users whose names are Helen or Simpson.

$\textit{finger HELEN}$

Login: hls Name: Helen Simpson.

...

$\textit{finger simpson}$

Login: hls Name: Helen Simpson.

...

$w$: Lists Users on the System

The $w$ utility displays a list of the users who are logged in. As discussed in the section on $\textit{who}$, the information that $w$ displays is useful when you want to communicate with someone at your installation.

The first column in Figure 3-13 shows that Alex, Jenny, and Scott are logged in. The second column shows the device number that each person's terminal is connected to. The third column shows the system that a remote user is logged in from. The fourth column shows the time each person logged in. The fifth column indicates how long each person has been idle (how much time has elapsed since the user pressed a key on the keyboard). The next two columns give measures of how much computer processor time each person has used during this login session and on the task that is running. The last column shows the command each person is running.

The first line that the $w$ utility displays includes the time of day, the period of time the computer has been running (in days, hours, and minutes), the number of users logged in, and the load average (how busy the system is). The three load average numbers represent the number of jobs waiting to run, averaged over the past 1, 5, and 15 minutes. Use the $\textit{uptime}$ utility to display just this line. Table 3-1 compares the $w$, $\textit{who}$, and $\textit{finger}$ utilities.

Figure 3-13. The $w$ utility

Communicating with Other Users

The utilities discussed in this section exchange messages and files with other users either interactively or through email.

**write: Sends a Message**

The `write` utility sends a message to another user who is logged in. When you and another user use `write` to send messages to each other, you establish two-way communication. Initially a `write` command (Figure 3-14) displays a banner on the other user's terminal, saying that you are about to send a message.

The syntax of a `write` command line is

```
write
username [terminal]
```

(Figure 3-14. The `write` utility I)

```
$ write alex
   Hi Alex, are you there? o
```

(Figure 3-15. The `write` utility II)

```
$ write alex
   Hi Alex, are you there? o
```

Message from alex@bravo.example.com on pts/0 at 16:23 ...

Yes Jenny, I'm here. o

The `username` is the login name of the user you want to communicate with. The `terminal` is an optional terminal name that is useful if the user is logged in more than once. You can display the login and terminal names of the users who are logged in on your system by using `who`, `w`, or `finger`.

To establish two-way communication with another user, you and the other user must each execute `write`, specifying the other's login name as the `username`. The `write` utility then copies text, line by line, from one keyboard/display to the other (Figure 3-15). Sometimes it helps to establish a convention, such as typing `o` (for over) when you are ready for the other person to type and typing `oo` (for over and out) when you are ready to end the conversation. When you want to stop communicating with the other user, press CONTROL-D at the beginning of a line. Pressing CONTROL-D tells `write` to quit, displays `EOF` (end of file) on the other user's terminal, and returns you to the shell. The other user must do the same.

If the `Message from`... banner appears on your screen and obscures something you are working on, press
CONTROL-L or CONTROL-R to refresh the screen and remove the banner. Then you can clean up, exit from your work, and respond to the person who is writing to you. You just have to remember who is writing to you, because the banner will no longer appear on the screen.

**mesg**: Denies or Accepts Messages

Give the following command when you do not wish to receive messages from another user:

```
$ mesg n
```

If Alex had given this command before Jenny tried to send him a message, she would have seen the following:

```
$ write alex
Permission denied
```

You can allow messages again by entering `mesg y`. Give the command `mesg` by itself to display `is y` (for yes, messages are allowed) or `is n` (for no, messages are *not* allowed).
Email

You can use email, or electronic mail, to send and receive letters, memos, reminders, invitations, and even junk mail (unfortunately). Email can also transmit binary data, such as pictures or compiled code, as attachments. An attachment is a file that is attached to, but is not part of, a piece of email. Attachments are frequently opened by programs that are called by your mail program, so you may not be aware that they are not an integral part of an email message.

You can use email to communicate with users on your system and, if your installation is part of a network, with other users on the network. If you are connected to the Internet, you can communicate electronically with users around the world.

Email utilities differ from write in that email utilities can send a message when the recipient is not logged in. These utilities can also send the same message to more than one user at a time.

Many mail programs are available for Linux, including the original character-based mail program, Netscape/Mozilla mail, pine, mail through emacs, Kmail, evolution, and exmh, which are supplied with many Linux distributions. Another popular graphical mail program is sylpheed (sylpheed.good-day.net).

You can use two programs to make any mail program easier to use and more secure. The procmail program (www.procmail.org) creates and maintains mail servers and mailing lists; preprocesses mail by sorting it into appropriate files and directories; starts various programs depending on the characteristics of incoming mail; forwards mail; and so on. The GNU Privacy Guard (gpg or GNUpg) encrypts and decrypts email and makes it almost impossible for an unauthorized person to read.

Network addresses

If your system is part of a LAN, you can generally send mail to and receive mail from users on other systems on the LAN by using their login names. Someone sending Alex email on the Internet would need to specify his domain name (page 873) along with his login name. Use the following address to send email to the author of this book: mgs@sobell.com.
Chapter Summary

The utilities introduced in this chapter and Chapter 2 constitute a small but powerful subset of the many utilities available on a typical Linux system. Because you will use them frequently and because they are integral to the following chapters, it is important that you become comfortable using them.

The utilities listed in Table 3-2 manipulate, display, compare, and print files.

Table 3-2. File utilities

<table>
<thead>
<tr>
<th>Utility</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>cp</td>
<td>Copies one or more files (page 45)</td>
</tr>
<tr>
<td>diff</td>
<td>Displays the differences between two files (page 51)</td>
</tr>
<tr>
<td>file</td>
<td>Displays information about the contents of a file (page 52)</td>
</tr>
<tr>
<td>grep</td>
<td>Searches file(s) for a string (page 48)</td>
</tr>
<tr>
<td>head</td>
<td>Displays the lines at the beginning of a file (page 49)</td>
</tr>
<tr>
<td>lpq</td>
<td>Displays a list of jobs in the print queue (page 47)</td>
</tr>
<tr>
<td>lpr</td>
<td>Places file(s) in the print queue (page 47)</td>
</tr>
<tr>
<td>lprm</td>
<td>Removes a job from the print queue (page 48)</td>
</tr>
<tr>
<td>mv</td>
<td>Renames a file or moves file(s) to another directory (page 46)</td>
</tr>
<tr>
<td>sort</td>
<td>Puts a file in order by lines (page 50)</td>
</tr>
<tr>
<td>tail</td>
<td>Displays the lines at the end of a file (page 49)</td>
</tr>
<tr>
<td>uniq</td>
<td>Displays the contents of a file, skipping successive duplicate lines (page 51)</td>
</tr>
</tbody>
</table>

To reduce the amount of disk space a file occupies, you can compress it with the bzip2 utility. The compression works especially well on files that contain patterns, such as most text files, but reduces the size of almost all files. The inverse of bzip2, bunzip2, restores a file to its original, decompressed form. Table 3-3 lists utilities that compress and decompress files. The bzip2 utility is the most efficient of these.

Table 3-3. (De)compression utilities

<table>
<thead>
<tr>
<th>Utility</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>bunzip2</td>
<td>Returns a file compressed with bzip2 to its original size and format (page 57)</td>
</tr>
<tr>
<td>bzcat</td>
<td>Displays a file compressed with bzip2 (page 57)</td>
</tr>
<tr>
<td>bzip2</td>
<td>Compresses a file (page 56)</td>
</tr>
<tr>
<td>compress</td>
<td>Compresses a file (not as well as gzip) (page 58)</td>
</tr>
<tr>
<td>gunzip</td>
<td>Returns a file compressed with gzip or compress to its original size and format (page 58)</td>
</tr>
<tr>
<td>gzip</td>
<td>Compresses a file (page 58)</td>
</tr>
<tr>
<td>zcat</td>
<td>Displays a file compressed with gzip (page 58)</td>
</tr>
</tbody>
</table>

An archive is a file, usually compressed, that contains a group of files. The tar utility (Table 3-4) packs and unpacks archives. The filename extensions .tar.bz2, .tar.gz, and .tgz identify compressed tar archive files and are often seen on software packages obtained over the Internet.
Table 3-4. Archive utility

<table>
<thead>
<tr>
<th>Utility</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>tar</td>
<td>Creates or extracts files from an archive file (page 58)</td>
</tr>
</tbody>
</table>

The utilities listed in Table 3-5 determine the location of a utility on the local system. For example, they can display the pathname of a utility or a list of C++ compilers available on the system.

Table 3-5. Location utilities

<table>
<thead>
<tr>
<th>Utility</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>apropos</td>
<td>Searches the man page one-line descriptions for a keyword (page 62)</td>
</tr>
<tr>
<td>slocate</td>
<td>Searches for files on the local system (page 63)</td>
</tr>
<tr>
<td>whereis</td>
<td>Displays the full pathnames of a utility, source code, or man page (page 61)</td>
</tr>
<tr>
<td>which</td>
<td>Displays the full pathname of a command you can run (page 61)</td>
</tr>
</tbody>
</table>

Table 3-6 lists utilities that display information about other users. You can easily learn a user's full name, the user's login status, the login shell of the user, and other information maintained by the system.

Table 3-6. User and system information utilities

<table>
<thead>
<tr>
<th>Utility</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>finger</td>
<td>Displays detailed information about users, including their full names (page 64)</td>
</tr>
<tr>
<td>w</td>
<td>Displays detailed information about users who are logged in (page 66)</td>
</tr>
<tr>
<td>who</td>
<td>Displays information about users who are logged in (page 64)</td>
</tr>
</tbody>
</table>

The utilities shown in Table 3-7 can help you stay in touch with other users on the local network.

Table 3-7. User communication utilities

<table>
<thead>
<tr>
<th>Utility</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>mesg</td>
<td>Permits or denies messages sent by write (page 68)</td>
</tr>
<tr>
<td>write</td>
<td>Sends a message to another user who is logged in (page 67)</td>
</tr>
</tbody>
</table>

Table 3-8 lists miscellaneous utilities.

Table 3-8. Miscellaneous utilities

<table>
<thead>
<tr>

<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>Displays the current date and time (page 54)</td>
</tr>
<tr>
<td>echo</td>
<td>Copies its arguments (page 861) to the screen (page 53)</td>
</tr>
</tbody>
</table>
Exercises

1. What commands can you use to determine who is logged in on a specific terminal?

2. How can you keep other users from using `write` to communicate with you? Why would you want to?

3. What happens when you give the following commands if the file named `done` already exists?

   ```
   $ cp to_do done
   $ mv to_do done
   ```

4. How can you find out which utilities are available on your system for editing files? Which utilities are available for editing on your system?

5. How can you find the phone number for Ace Electronics in a file named `phone` that contains a list of names and phone numbers? Which command can you use to display the entire file in alphabetical order? How can you remove adjacent duplicate lines from the file? How can you remove all duplicates?

6. What happens when you use `diff` to compare two binary files that are not identical? (You can use `gzip` to create the binary files.) Explain why the `diff` output for binary files is not the same as the `diff` output for ASCII files.

7. Create a `.plan` file in your home directory. Does `finger` on your system display the contents of your `.plan` file?

8. What is the result of giving the `which` utility the name of a command that resides in a directory that is not in your search path?

9. Are any of the utilities discussed in this chapter found in more than one directory on your system? If so, which ones?

10. Experiment by calling the `file` utility with names of files in `/usr/bin`. How many different types of files are there?

11. Which command can you use to look at the first few lines of a file named `status.report`? Which command can you use to look at the end of the file?
Advanced Exercises

12. Re-create the colors.1 and colors.2 files used in Figure 3-8 on page 52. Test your files by running diff on them, and see whether you get the same results as in the figure.

13. Try giving these two commands.

   $ echo cat
   $ cat echo

   Explain the differences between them.

14. Repeat exercise 5 using the file phone.gz, a compressed version of the list of names and phone numbers. Try to consider more than one approach to answer each question, and explain how you made your choices.

15. Find existing files or create files that

   a. gzip compresses by more than 80 percent
   b. gzip compresses by less than 10 percent
   c. get larger when compressed with gzip

   Use ls -l to determine the sizes of the files in question. Can you characterize the files in a, b, and c?

16. Some mailers—particularly older ones—are not able to handle binary files. Suppose that you are mailing a file that has been compressed with gzip, which produces a binary file, and you do not know what mailer the recipient is using. Refer to the man page for uuencode, which converts a binary file to an ASCII file. Learn about the utility and how to use it.

   a. Convert a compressed file to ASCII, using uuencode. Is the encoded file larger or smaller than the compressed file? Explain. (If uuencode is not on your system, you can download it from rpmfind.net; it is part of the GNU sharutils package.)

   b. Would it ever make sense to use uuencode on a file before compressing it? Explain.
Chapter 4. The Linux Filesystem

IN THIS CHAPTER

The Hierarchical Filesystem 76

Directory and Ordinary Files 77

Absolute Pathnames 83

Relative Pathnames 84

Working with Directories 88

Access Permissions 91

Hard Links 97

Symbolic Links 99

A Filesystem is a data structure (870) that usually resides on part of a disk and that holds directories of files. Filesystems store user and system data that are the basis of users' work on the system and the system's existence. This chapter discusses the organization and terminology of the Linux filesystem, defines ordinary and directory files, and explains the rules for naming them. It also shows how to create and delete directories, move through the filesystem, and use pathnames to access files in various directories. It includes a discussion of important files and directories as well as various types of files and ways to work with them. In addition, this chapter covers file access permissions, which allow you to share selected files with other users, and links, which can make a single file appear in more than one directory.

In addition to reading this chapter, you may want to refer to the df, fsck, mkfs, and tune2fs utilities in Part V for more information on filesystems.
The Hierarchical Filesystem

Family tree

A hierarchical (878) structure frequently takes the shape of a pyramid. One example of this type of structure is found by tracing a family's lineage: A couple has a child, who may in turn have several children, each of whom may have more children. This hierarchical structure (shown in Figure 4-1) is called a family tree.

Figure 4-1. A family tree

Directory tree

Like the family tree it resembles, the Linux filesystem is called a tree. It consists of a set of connected files. This structure allows you to organize files so you can easily find any particular one. On a standard Linux system, each user starts with one directory, to which the user can add subdirectories to any desired level. By creating multiple levels of subdirectories, a user can expand the structure as needed.

Subdirectories

Typically each subdirectory is dedicated to a single subject, such as a person, project, or event. The subject dictates whether a subdirectory should be subdivided further. For example, Figure 4-2 shows a secretary's subdirectory named correspond. This directory contains three subdirectories: business, memos, and personal. The business directory contains files that store each letter the secretary types. If you expect many letters to go to one client, as is the case with milk_co, you can dedicate a subdirectory to that client.

Figure 4-2. A secretary's directories
One major strength of the Linux filesystem is its ability to adapt to users' needs. You can take advantage of this strength by strategically organizing your files so they are most convenient and useful for you.
Directory and Ordinary Files

Like a family tree, the tree representing the filesystem is usually pictured upside down, with its root at the top. Figures 4-2 and 4-3 show that the tree "grows" downward from the root, with paths connecting the root to each of the other files. At the end of each path is either an ordinary file or a directory file. Ordinary files, or simply files, appear at the ends of paths that cannot support other paths. Directory files, usually referred to as directories or folders, are points that other paths can branch off from. (Figures 4-2 and 4-3 show some empty directories.) When you refer to the tree, up is toward the root and down is away from the root. Directories directly connected by a path are called parents (closer to the root) or children (farther from the root). A pathname is a series of names that traces a path along branches from one file to another.

Figure 4-3. Directories and ordinary files

Filenames

Every file has a filename. The maximum length of a filename varies with the type of filesystem; Linux includes support for several types of filesystems. Most of today's filesystems allow you to create files with names up to 255 characters in length, but some older filesystems may restrict you to 14-character names. Although you can use almost any character in a filename, you will avoid confusion if you choose characters from the following list:

- Uppercase letters (A-Z)
- Lowercase letters (a-z)
- Numbers (0-9)
- Underscore (_)
- Period (.)
- Comma (, )
The *root* directory is always named `/` (slash) and referred to by this single character. No other file can use this name or have a `/` in its name. However, in a pathname, which is a string of filenames including directory names, the slash separates filenames (page 83).

Like the children of one parent, no two files in the same directory can have the same name. (Parents give their children different names because it makes good sense, but Linux requires it.) Files in different directories, like children of different parents, can have the same name.

The filenames you choose should mean something. Too often a directory is filled with important files with such unhelpful names as `hold1`, `wombat`, and `junk`, not to mention `foo` and `foobar`. Such names are poor choices because they do not help you recall what you stored in a file. The following filenames conform to the suggested syntax and convey information about the contents of the file:

- `correspond`
- `january`
- `davis`
- `reports`
- `2001`
- `acct_payable`

**Filename length**

When you share files with users on other systems, you may need to make long filenames differ within the first 14 characters. If you keep the filenames short, they are easy to type; later you can add extensions to them without exceeding the 14-character limit imposed by some filesystems. The disadvantage of short filenames is that they are typically less descriptive than long filenames. When you share files with systems running DOS or older versions of Windows, you must respect the 8-character filename body length and 3-character filename extension length imposed by those systems.

Long filenames enable you to assign descriptive names to files. To help you select among files without typing entire filenames, shells support filename completion. For more information about this feature, see the "Filename completion" tip on page 45.

You can use uppercase and/or lowercase letters within filenames. Linux is case sensitive, so files named `JANUARY`, `January`, and `january` represent three distinct files.

*caution: Do not use SPACES within filenames*

Although you can use SPACES within filenames, it is a poor idea. Because a SPACE is a special character, you must quote it on a command line. Quoting a character on a command line can be difficult for a novice user and cumbersome for an experienced user. Use periods or underscores instead of SPACES: `joe.05.04.26`, `new_stuff`.

**Filename Extensions**
In the filenames listed in Table 4-1, filename extensions help describe the contents of the file. A filename extension is the part of the filename following an embedded period. Some programs, such as the C programming language compiler, depend on specific filename extensions. In most cases, however, filename extensions are optional. Use extensions freely to make filenames easy to understand. You can use several periods within the same filename—for example, notes.4.10.01 or files.tar.gz.

Table 4-1. Filename extensions

<table>
<thead>
<tr>
<th>Filename</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.c</td>
<td>A C programming language source file</td>
</tr>
<tr>
<td>compute.o</td>
<td>The object code for the program</td>
</tr>
<tr>
<td>compute</td>
<td>The same program as an executable file</td>
</tr>
<tr>
<td>memo.0410.txt</td>
<td>A text file</td>
</tr>
<tr>
<td>memo.pdf</td>
<td>A PDF file; view with xpdf under a GUI</td>
</tr>
<tr>
<td>memo.ps</td>
<td>A PostScript file; view with gs under a GUI</td>
</tr>
<tr>
<td>memo.Z</td>
<td>A file compressed with compress (page 58); use uncompress or gunzip (page 58) to decompress</td>
</tr>
<tr>
<td>memo.tgz or memo.tar.gz</td>
<td>A tar (page 58) archive of files compressed with gzip (page 58)</td>
</tr>
<tr>
<td>memo.gz</td>
<td>A file compressed with gzip (page 58); view with zcat or decompress with gunzip (both on page 58)</td>
</tr>
<tr>
<td>memo.bz2</td>
<td>A file compressed with bzip2 (page 56); view with bzcat or decompress with bunzip2 (both on page 57)</td>
</tr>
<tr>
<td>memo.html</td>
<td>A file meant to be viewed using a Web browser, such as Mozilla</td>
</tr>
<tr>
<td>photo.jpg or photo.gif</td>
<td>A file containing graphical information, such as a picture (also .jpeg )</td>
</tr>
</tbody>
</table>

Invisible Filenames

A filename that begins with a period is called an invisible filename (or an invisible file or sometimes a hidden file) because ls does not normally display it. The command ls [a displays all filenames, even invisible ones. Names of startup files (page 83) usually begin with a period so that they are invisible and do not clutter a directory listing. The .plan file (page 65) is also invisible. Two special invisible entries—a single and double period ( . and . .)—appear in every directory (page 85).

mkdir: Creates a Directory

The mkdir utility creates a directory. The argument (861) to mkdir becomes the pathname of the new directory. The following examples develop the directory structure shown in Figure 4-4. In the figure the directories that are added are a lighter shade than the others and are connected by dashes.

Figure 4-4. The file structure developed in the examples
In Figure 4-5, ls shows the names of the files Alex has been working with in his home directory: demo, names, and temp. Using mkdir, Alex then creates a directory named literature as a child of the /home/alex directory. When you use mkdir, enter the pathname of your home directory (page 82) in place of /home/alex. The second ls verifies the presence of the new directory.

Figure 4-5. The mkdir utility

$ ls
demo names temp

$ mkdir /home/alex/literature

$ ls
demo literature names temp

$ ls -F
demo literature/ names temp

$ ls literature

$ 

You can use the -F option with ls to display a slash after the name of each directory and an asterisk after each executable file (shell script, utility, or program). When you call it with an argument that is the name of a directory, ls lists the contents of the directory. If the directory is empty, ls does not display anything.
The working directory

**pwd**

While you are logged in on a character-based interface to a Linux system, you are always associated with a directory. The directory you are associated with, or are working in, is called the *working directory* or *current directory*. Sometimes this association is referred to in a physical sense: "You are in (or working in) the *jenny* directory." The **pwd** command displays the pathname of the working directory.

To access any file in the working directory, you need only a simple filename. To access a file in another directory, you **must** use a pathname.

**Significance of the Working Directory**

Typing a long pathname is tedious and increases the chance of making a mistake. This possibility is less likely under a GUI, where you click filenames or icons. You can choose a working directory for any particular task to reduce the need for long pathnames. Your choice of a working directory does not allow you to do anything you could not do otherwise. Instead, it simply makes some operations easier.

Refer to **Figure 4-6** as you read this paragraph. Files that are children of the working directory can be referenced by simple filenames. Grandchildren of the working directory can be referenced by short relative pathnames: two filenames separated by a slash. When you manipulate files in a large directory structure, short relative pathnames can save time and aggravation. If you choose a working directory that contains the files used most often for a particular task, you need to use fewer long, cumbersome pathnames.

**Figure 4-6. Relative pathnames**

[Diagram of directory structure]

**Home directory**

When you first log in on a Linux system, your working directory is your *home directory*. To display the pathname
When you first log in on a Linux system, your working directory is your home directory. To display the pathname of your home directory, use \texttt{pwd} just after you log in (see Figure 4-7).

When used without any arguments, the \texttt{ls} utility displays a list of the files in the working directory. Because your home directory has been the only working directory you have used so far, \texttt{ls} has always displayed a list of files in your home directory. (All the files you have created up to this point were created in your home directory.)

\textbf{cd: Changes to Another Working Directory}

The \texttt{cd} (change directory) utility makes another directory the working directory but does not change the contents of the working directory. The first \texttt{cd} command in Figure 4-8 makes the /home/alex/literature directory the working directory, as verified by \texttt{pwd}.

When used without an argument, \texttt{cd} makes your home directory the working directory, as it was when you first logged in. The second \texttt{cd} command in Figure 4-8 does not have an argument and makes Alex's home directory the working directory.

\begin{figure}
\centering

Last login: Wed Oct 20 11:14:21 from bravo

$ pwd
/home/alex

$ cd /home/alex/literature
$ pwd
/home/alex/literature
$ cd
$ pwd
/home/alex
\end{verbatim}

\begin{figure}
\centering
\includegraphics[width=\textwidth]{figure4-8.png}
\caption{\texttt{cd} changes your working directory}
\end{figure}

\begin{verbatim}
$ cd /home/alex/literature
$ pwd
/home/alex/literature
$ cd
$ pwd
/home/alex
\end{verbatim}

\textbf{tip: The working directory versus your home directory}

The working directory is not the same as your home directory. Your home directory remains the same for
the duration of your session and usually from session to session. Each time immediately after you log in, you are working in the same directory: your home directory.

Unlike your home directory, the working directory can change as often as you like. You have no set working directory, which is why some people refer to it as the current directory. When you log in and until you change directories by using cd, your home directory is your working directory. If you were to change directories to Scott's home directory, then Scott's home directory would be your working directory.

**Startup files**

Startup files, which appear in your home directory, give the shell and other programs information about you and your preferences. Frequently, one of these files tells the shell what kind of terminal you are using and executes the stty (set terminal) utility to establish your line kill and erase keys.

Either you or the system administrator can put a shell startup file containing shell commands in your home directory. The shell executes the commands in this file each time you log in. Because the startup files have invisible filenames, you must use the ls -a command to see whether one is in your home directory. See pages 257 and 342 for more information about startup files.

**Absolute Pathnames**

Every file has a pathname. Figure 4-9 shows the pathnames of directories and ordinary files in part of a filesystem hierarchy. An absolute pathname always starts with a slash (/), the name of the root directory. You can build the absolute pathname of a file by tracing a path from the root directory through all the intermediate directories to the file. String all the filenames in the path together, separating each from the next with a slash (\/) and preceding the entire group of filenames with a slash (/). This path of filenames is called an absolute pathname because it locates a file absolutely by tracing a path from the root directory to the file. The part of a pathname following the final slash is called a simple filename or just filename.

**Figure 4-9. Absolute pathnames**
Another form of absolute pathname begins with a tilde (\textasciitilde{}), which represents a home directory. For more information refer to "\textasciitilde{} (Tilde) in Pathnames" on page 89.

**Relative Pathnames**

A relative pathname traces a path from the working directory to a file. The pathname is relative to the working directory. Any pathname that does not begin with the root directory (/) or a tilde (\textasciitilde{}) is a relative pathname. Like absolute pathnames, relative pathnames can describe a path through many directories.

Alex could have created the literature directory in Figure 4-5 more easily by using a relative pathname:

$ \texttt{pwd}$

/home/alex

$ \texttt{mkdir literature}$

The \texttt{pwd} command shows that Alex's home directory (/home/alex) is the working directory. The \texttt{mkdir} utility displays an error message if a directory or file named literature exists: You cannot have two files or directories with the same name in the same directory. The pathname used in this example is a simple filename—a kind of relative pathname that specifies a file in the working directory.

The following commands show two ways to create the promo directory as a child of the newly created literature directory. The first way works when /home/alex is the working directory and uses a relative pathname.

$ \texttt{pwd}$

/home/alex

$ \texttt{mkdir literature/promo}$

\textbf{caution: When using a relative pathname, know which directory is the working directory}

The location of the file that you are accessing with a relative pathname depends on (is relative to) the working directory. Always make sure you know which directory is the working directory before you use a relative pathname. Use \texttt{pwd} to verify the directory. If you are using \texttt{mkdir} and you are not where you think you are in the file hierarchy, the new directory will end up in an unexpected location.

It does not matter which directory is the working directory when you use an absolute pathname.

The second way uses an absolute pathname:

$ \texttt{mkdir /home/alex/literature/promo}$

Use the \texttt{p} (parents) option to \texttt{mkdir} to create both the literature and promo directories with a single command.
$ pwd
/home/alex

$ ls
demo  names  temp

$ mkdir -p literature/promo

or

$ mkdir -p /home/alex/literature/promo

The . and .. Directory entries

The `mkdir` utility automatically puts two entries in each directory it creates: a single period (.) and a double period (..), representing the directory itself and the parent directory, respectively. These entries are invisible because each of their filenames begins with a period.

Because `mkdir` automatically places these entries in every directory, you can rely on their presence. The . is synonymous with the pathname of the working directory and can be used in its place; .. is synonymous with the pathname of the parent of the working directory.

With the `literature` directory as the working directory, the following example uses .. three times: first to list the contents of the parent directory (`/home/alex`), second to copy the `memoA` file to the parent directory, and third to list the contents of the parent directory again.

$ pwd
/home/alex/literature

$ ls ..
demo  literature  names  temp

$ cp memoA ..

$ ls ..
demo  literature  memoA  names  temp

While working in the `promo` directory, Alex can use a relative pathname to edit a file in his home directory. Before calling the editor, Alex checks which directory he is in:

$ pwd
Virtually anywhere that a utility or program requires a filename or pathname, you can use an absolute or relative pathname or a simple filename. This usage holds true for `ls`, `vim`, `mkdir`, `rm`, and other Linux utilities.

**Important Standard Directories and Files**

Originally files on a Linux system were not located in standard places. The scattered files made it difficult to document and maintain a Linux system and just about impossible for someone to release a software package that would compile and run on all Linux systems. The first standard for the Linux filesystem, the FSSTND (Linux Filesystem Standard), was released on February 14, 1994. In early 1995 work was started on a broader standard covering many UNIX-like systems: FHS (Linux Filesystem Hierarchy Standard). More recently, FHS has been incorporated in LSB (Linux Standard Base), a workgroup of FSG (Free Standards Group). Figure 4-10 shows the locations of some important directories and files as specified by FHS. The significance of many of these directories will become clear as you continue reading.

**Figure 4-10. A typical FHS-based Linux system file structure**

The following list describes the directories shown in Figure 4-10, some of the directories specified by FHS, and some other directories. Most Linux distributions do not use all the directories specified by FHS. You cannot always determine the function of a directory by its name. For example, although `/opt` stores add-on software, `/etc/opt` stores configuration files for the software in `/opt`.

- **/ Root** The root directory, present in all Linux system file structures, is the ancestor of all files in the filesystem.
- **/bin** Essential command binaries Holds the files needed to bring the system up and run it when it first comes up in single-user mode.
- **/boot** Static files of the boot loader Contains most of the files needed to boot the system.
- **/dev** Device files Contains all files that represent peripheral devices, such as disk drives, terminals, and printers.
- **/etc** Machine/local system configuration Holds administrative, configuration, and other system files. One of the most important is `/etc/passwd`, which contains a list of all users who have permission to use the system.
- **/etc/X11** Machine/local configuration for the X Window System
- **/etc/opt** Configuration files for add-on software packages kept in /opt
- **/home** User home directories Each user's home directory is typically one of many subdirectories of the `/home` directory. As an example, assuming that users' directories are under `/home`, the absolute pathname of Jenny's home directory is `/home/jenny`. On some systems the users' directories may
not be under /home but instead might be spread among /inhouse and /clients.

/lib  Shared libraries and kernel modules
/lib/modules  Loadable kernel modules
/mnt  Mount point for temporary mounting of filesystems
/opt  Add-on software packages (optional packages)
/proc  Kernel and process information virtual filesystem
/root  Home directory for root
/sbin  Essential system binaries Utilities used for system administration are stored in /sbin and /usr/sbin. The /sbin directory includes utilities needed during the booting process, and /usr/sbin holds utilities used after the system is up and running. In older versions of Linux, many system administration utilities were scattered through several directories that often included other system files (/etc, /usr/bin, /usr/adm, /usr/include).
/tmp  Temporary files Used to hold temporary files.
/usr  Second major hierarchy Traditionally includes subdirectories that contain information used by the system. Files in /usr subdirectories do not change often and may be shared by multiple systems.
/usr/bin  Most user commands Contains the standard Linux utility programs—that is, binaries that are not needed in single-user mode.
/usr/bin/X11  Symbolic link to /usr/X11R6/bin
/usr/games  Games and educational programs
/usr/include  Header files included by C programs
/usr/include/X11  Symbolic link to /usr/X11R6/include/X11
/usr/lib  Libraries
/usr/lib/X11  Symbolic link to /usr/X11R6/lib/X11
/usr/local  Local hierarchy Holds locally important files and directories that are added to the system. Subdirectories can include bin, games, include, lib, sbin, share, and src.
/usr/man  Online manuals
/usr/sbin  Nonvital system administration binaries See /sbin.
/usr/share  Architecture-independent data Subdirectories can include dict, doc, games, info, locale, man, misc, terminfo, and zoneinfo.
/usr/share/doc  Miscellaneous documentation
/usr/share/info  GNU info system’s primary directory
/usr/src  Source code
/usr/X11R6  X Window System, version 11 release 6
/var  Variable data Files with contents that vary as the system runs are found in subdirectories under /var. The most common examples are temporary files, system log files, spooled files, and user mailbox files. Subdirectories can include cache, lib, lock, log, opt, run, spool, tmp, and yp. Older versions of Linux scattered such files through several subdirectories of /usr (/usr/adm, /usr/mail, /usr/spool, /usr/tmp).
/var/log  Log files Contains lastlog (a record of the last login by each user), messages (system messages from syslogd), and wtmp (a record of all logins/logouts).
/var/spool  Spoofed application data Contains anacron, at, cron, lpd, mail, mqueue, news, samba, and uucp. The file /var/spool/mail typically has a symbolic link in /var.
Working with Directories

This section covers deleting directories, copying and moving files between directories, and moving directories. It also describes how to use pathnames to make your work with Linux easier.

**rmdir: Deletes a directory**

The `rmdir` (remove directory) utility deletes a directory. You cannot delete the working directory or a directory that contains files other than . and .. entries. If you need to delete a directory with files in it, first use `rm` to delete the files and then delete the directory. You do not have to (nor can you) delete the . and .. entries; `rmdir` removes them automatically. The following command deletes the directory that was created in Figure 4-5 on page 81:

```
$ rmdir /home/alex/literature
```

The `rm` utility has a `r` option (`rm r filename`) that recursively deletes files, including directories, within a directory as well as the directory itself.

**caution: Use rm r carefully, if at all**

Although `rm r` is a handy command, you must use it carefully. Do not use it with an ambiguous file reference such as *.*. It is quite easy to wipe out your entire home directory with a single short command.

**Pathnames**
touch

Use a text editor to create a file named letter if you want to experiment with the examples that follow. Or you can use touch to create an empty file:

$ touch letter

With /home/alex as the working directory, the following example uses cp with a relative pathname to copy the file letter to the /home/alex/literature/promo directory. The copy of the file has the simple filename letter.0610:

$ pwd
/home/alex

$ cp letter literature/promo/letter.0610

If Alex does not change to another directory, he can use vim to edit the copy of the file he just made:

$ vim literature/promo/letter.0610

If Alex does not want to use a long pathname to specify the file, he can use cd to make promo the working directory before calling vim:

$ cd literature/promo
$ pwd
/home/alex/literature/promo
$ vim letter.0610

To make the parent of the working directory (named /home/alex/literature) become the new working directory, Alex can give the following command, which takes advantage of the .. directory entry:

$ cd ..
$ pwd
/home/alex/literature

~ (Tilde) in pathnames
The shell expands the characters ~/ (a tilde followed by a slash) at the start of a pathname into the pathname of your home directory. Using this shortcut, you can display your .bashrc startup file (page 258) with the following command, no matter which directory is your working directory:

$ less ~/.bashrc

A tilde quickly references paths that start with your or someone else's home directory. The shell expands a tilde followed by a login name at the beginning of a pathname into the pathname of that user's home directory. Assuming he has permission to do so, Alex can examine Scott's ~/bashrc file with the following command:

$ less ~scott/.bashrc

Refer to "Tilde expansion" on page 326 for more information.

mv, cp: Moves or Copies a File

Chapter 3 discussed the use of mv to rename files. However, mv is more general than that: You can use this utility to move files from one directory to another (change the pathname of a file) as well as to change a simple filename. When used to move one or more files to a new directory, the mv command has this syntax:

```
mv existing-file-list directory
```

If the working directory is /home/alex, Alex can use the following command to move the files names and temp from the working directory to the literature directory:

$ mv names temp literature

This command changes the absolute pathnames of the names and temp files from /home/alex/names and /home/alex/temp to /home/alex/literature/names and /home/alex/literature/temp, respectively (Figure 4-11). Like most Linux commands, mv accepts either absolute or relative pathnames.

Figure 4-11. Using mv to move names and temp
As you work with Linux and create more and more files, you will need to create directories using `mkdir` to keep the files organized. The `mv` utility is a useful tool for moving files from one directory to another as you develop your file tree. The `cp` utility works in the same way that `mv` does, but it makes copies of the `existing-file-list` in the specified `directory`.

**mv: Moves a Directory**

Just as it moves ordinary files from one directory to another, so `mv` can move directories. The syntax is similar except that you specify one or more directories, not ordinary files, to move:

```
mv  
existing-directory-list new-directory
```

If `new-directory` does not exist, the `existing-directory-list` must contain just one directory name, which `mv` changes to `new-directory` (`mv` renames the directory). Although directories can be renamed using `mv`, their contents cannot be copied with `cp` unless you use the `-r` option. Refer to the explanations of `tar` (page 786) and `cpio` (page 619) for other ways to copy and/or move directories.
Access permissions

Three types of users can access a file: the owner of the file (owner), a member of a group to which the owner belongs (group), and everyone else (other). A user can attempt to access an ordinary file in three ways: by trying to read from, write to, or execute it. Three types of users, each of whom is able to access a file in three ways, equals a total of nine possible ways to access an ordinary file.

**ls -l: Displays Permissions**

When you call `ls` with the `-l` option and the name of an ordinary file, `ls` displays a line of information about the file. The following example displays information for two files. The file `letter.0610` contains the text of a letter, and `check_spell` contains a shell script, a program written in a high-level shell programming language:

```
$ ls -l letter.0610 check_spell
-rw-r--r-- 1 alex  pubs  3355  May  2 10:52 letter.0610
-rwxr-xr-x 2 alex  pubs   852  May  5 14:03 check_spell
```

From left to right, the lines that an `ls -l` command displays contain the following information (refer to **Figure 4-12**):

- The type of file (first character)
- The file's access permissions (the next nine characters)
- The number of links to the file (page 96)
- The name of the file's owner (usually the person who created the file)
- The name of the group that has group access to the file
- The size of the file in characters (bytes)
- The date and time the file was created or last modified
- The name of the file

**Figure 4-12. The columns displayed by the ls -l command**

The type of file (first column) for `letter.0610` is a hyphen (l) because it is an ordinary file (directory files have a d in
The type of file (first column) for letter.0610 is a hyphen (d) because it is an ordinary file (directory files have a d in this column).

The next three characters represent the access permissions for the owner of the file: r indicates read permission and w indicates write permission. The x in the next column indicates that the owner does not have execute permission; otherwise, an x would appear here.

In a similar manner the next three characters represent permissions for the group, and the final three characters represent permissions for other (everyone else). In the preceding example, the owner of letter.0610 can read from and write to the file, whereas the group and others can only read from the file and no one is allowed to execute it. Although execute permission can be allowed for any file, it does not make sense to assign execute permission to a file that contains a document, such as a letter. The check_spell file is an executable shell script, and execute permission is appropriate. (The owner, the group, and others all have execute access permission.)

**chmod: Changes Access Permissions**

The owner of a file controls which users have permission to access the file and how they can access it. When you own a file, you can use the chmod (change mode) utility to change access permissions for that file. In the following example, chmod adds (+) read and write permission (rw) for all (a) users:

```bash
$ chmod a+rw letter.0610
$ ls -l letter.0610
-rw-rw-rw- 1 alex pubs 3355  May  2 10:52 letter.0610
```

**tip: You must have read permission to execute a shell script**

Because a shell needs to read a shell script (an ASCII file containing shell commands) before it can execute the commands within the script, you must have read permission to the file containing the script to execute it. You also need execute permission to execute a shell script directly on the command line. Binary (program) files do not need to be read; they are executed directly. You need only execute permission to run a binary (nonshell) program.

In the next example, chmod removes (o) read and execute (rx) permissions for users other (o) than the owner of the file (Alex) and members of the group associated with the file (pubs):

```bash
$ chmod o-rx check_spell
$ ls -l check_spell
-rwxr-x--- 2 alex pubs 852  May  5 14:03 check_spell
```

In addition to a (for all) and o (for other), you can use g (for group) and u (for user, although user refers to the owner of the file, who may or may not be the user of the file at any given time) in the argument to chmod. Refer to page 263 for more information on using chmod to make a file executable.

In addition to the symbolic arguments described in this section, you can use absolute, or numeric, arguments with chmod. See page 604 for information on absolute arguments and chmod in general.
The Linux file access permission scheme lets you give other users access to the files you want to share yet keep your private files confidential. You can allow other users to read from and write to a file (you may be one of several people working on a joint project). You can allow others only to read from a file (perhaps a project specification you are proposing). Or you can allow others only to write to a file (similar to an inbox or mailbox, where you want others to be able to send you mail but do not want them to read your mail). Similarly, you can protect entire directories from being scanned (covered shortly).

There is an exception to the access permissions just described. Anyone who knows the root password can log in as Superuser and have full access to all files, regardless of owner or access permissions.

**tip: chmod**: o for other, u for owner

When using chmod, many people assume that the o stands for owner; it does not. The o stands for other, whereas u stands for owner (user).

**Setuid and setgid permissions**

When you execute a file that has setuid (set user ID) permission, the process executing the file takes on the privileges of the file's owner. For example, if you run a setuid program that removes all files in a directory, you can remove files in any of the file owner's directories, even if you do not normally have permission to do so.

In a similar manner, setgid (set group ID) permission means that the process executing the file takes on the privileges of the group the file is associated with. The ls utility shows setuid permission by placing an s in the owner's executable position and setgid by placing an s in the group's executable position:

```
$ ls -l program1
-rwxr-xr-x   1 alex pubs 15828 Nov  5 06:28 program1
$ chmod u+s program1
$ ls -l program1
-rwsr-xr-x   1 alex pubs 15828 Nov  5 06:28 program1
$ chmod g+s program1
$ ls -l program1
-rwsr-sr-x   1 alex pubs 15828 Nov  5 06:28 program1
```

**security: Minimize use of setuid and setgid programs owned by root**

Executable files that are setuid and owned by root have Superuser privileges when they are run, even if they are not run by root. This type of program is very powerful because it can do anything that Superuser can do (that the program is designed to do). Similarly, executable files that are setgid and belong to the group root have extensive privileges.

Because of the power they hold and their potential for destruction, you should avoid creating and using setuid and setgid programs owned by root or belonging to the group root indiscriminately. Because of their inherent dangers, many sites do not allow these programs on their systems.
security: Do not write setuid shell scripts

Never give shell scripts setuid permission. Several techniques for subverting them are well known.

Directory access permissions

Access permissions have slightly different meanings when they are used with directories. Although the three types of users can read from or write to a directory, the directory cannot be executed. Execute access permission is redefined for a directory: It means that you can cd into the directory and/or examine files that you have permission to read in the directory. It has nothing to do with executing a file.

When you have only execute permission for a directory, you can use ls to list a file in the directory if you know its name. You cannot use ls without an argument to list the entire contents of the directory. In the following exchange, Jenny first verifies that she is logged on as herself. Then she checks the permissions on Alex's info directory and cd s into it. You can view the access permissions associated with a directory by running ls with the l (directory) and l (long) options:

$ who am i
jenny pts/7 Aug 21 10:02
$ ls -ld /home/alex/info
drwx-----x 2 alex pubs 512 Aug 21 09:31 /home/alex/info
$ ls -l /home/alex/info
ls: /home/alex/info: Permission denied

The d at the left end of the line displayed by ls indicates that /home/alex/info is a directory. Alex has read, write, and execute permissions; members of the pubs group have no access permissions; and other users have execute permission only as indicated by the x at the right end of the permissions. Because Jenny does not have read permission for the directory, the ls l command returns an error.

When Jenny specifies the names of the files she wants information about, she is not reading new directory information but searching for specific information, which she is allowed to do with execute access to the directory. She has read access to notes, so she has no problem using cat to display the file. She cannot display financial because she does not have read access to it:

$ ls -l /home/alex/info/financial /home/alex/info/notes
-rw------- 1 alex pubs 34 Aug 21 09:31 /home/alex/info/financial
-rw-r--r-- 1 alex pubs 30 Aug 21 09:32 /home/alex/info/notes

$ cat /home/alex/info/notes
This is the file named notes.
$ cat /home/alex/info/financial

cat: /home/alex/info/financial: Permission denied

Next Alex gives others read access to his info directory:

$ chmod o+r /home/alex/info

When Jenny checks her access permissions on info, she finds that she has both read and execute access to the directory. Now ls -l works just fine without arguments, but she still cannot read financial. (This is an issue of file permissions, not directory permissions.)

Finally, Jenny tries to create a file named newfile by using touch. If Alex were to give her write permission to the info directory, she would be able to create new files in it:

$ ls -ld /home/alex/info

drwx---r-x   2 alex pubs 512 Aug 21 09:31 /home/alex/info

$ ls -l /home/alex/info

total 8

-rw-------   1 alex pubs 34 Aug 21 09:31 financial

-rw-r--r--   1 alex pubs 30 Aug 21 09:32 notes

$ cat financial

cat: financial: Permission denied

$ touch /home/alex/info/newfile

touch: cannot touch '/home/alex/info/newfile': Permission denied
Links

A link is a pointer to a file. Each time you create a file using `vim`, `touch`, `cp`, or any other means, you are putting a pointer in a directory. This pointer associates a filename with a place on the disk. When you specify a filename in a command, you are indirectly pointing to the place on the disk that holds the information you want.

Sharing files can be useful when two or more people are working on the same project and need to share information. You can make it easy for other users to access one of your files by creating additional links to the file.

To share a file with another user, first give the user permission to read from and write to the file. (You may also have to change the access permission of the parent directory of the file to give the user read, write, and/or execute permission.) Once the permissions are set appropriately, the user can create a link to the file so that each of you can access the file from your separate file trees.

A link can also be useful to a single user with a large file tree. You can create links to cross-classify files in your file tree, using different classifications for different tasks. For example, if your file tree is the one depicted in Figure 4-2, you might have a file named `to_do` in each subdirectory of the `correspond` directory—that is, in `personal`, `memos`, and `business`. If you later find it difficult to keep track of everything you need to do, you can create a separate directory named `to_do` in the `correspond` directory and link each subdirectory's to-do list into that directory. For example, you could link the file named `to_do` in the `memos` directory to a file named `memos` in the `to_do` directory. This set of links is shown in Figure 4-13.

**Figure 4-13. Using links to cross-classify files**

![Diagram showing links]

Although it may sound complicated, this technique keeps all your to-do lists conveniently in one place. The appropriate list is easily accessible in the task-related directory when you are busy composing letters, writing memos, or handling personal business.

---

**tip: About the discussion of hard links**

Two kinds of links exist: hard links and symbolic (soft) links. Hard links are older and becoming dated. The section on hard links is marked as optional; you can skip it, although it discusses inodes and gives you insight into how the filesystem is structured.
optional: Hard Links

A hard link to a file appears as another file in the file structure. If the link appears in the same directory as the linked-to file, the links must have different filenames because two files in the same directory cannot have the same name.

`ln`: CREATES A HARD LINK

The `ln` (link) utility (without the `s` or `--symbolic` option) creates an additional hard link to an existing file using the following syntax:

```
ln existing-file new-link
```

The next command makes the link shown in Figure 4-14 by creating a new link named `/home/alex/letter` to an existing file named `draft` in Jenny's home directory:

```
$ pwd
/home/jenny

$ ln draft /home/alex/letter
```

Figure 4-14. Two links to the same file: `/home/alex/letter` and `/home/jenny/draft`

The new link appears in the `/home/alex` directory with the filename `letter`. In practice Alex may need to change directory and file permissions as shown in the previous section for Jenny to be able to access the file.
The **ln** utility creates an additional pointer to an existing file but does *not* make another copy of the file. Because there is only one file, the file status information—such as access permissions, owner, and the time the file was last modified—is the same for all links. Only the filenames differ. When Jenny modifies `/home/jenny/draft`, Alex sees the changes in `/home/alex/letter`.

### cp VERSUS ln

The following commands verify that **ln** does not make an additional copy of a file. Create a file, use **ln** to make an additional link to the file, change the contents of the file through one link, and verify the change through the other link:

```bash
$ cat file_a
This is file A.
$ ln file_a file_b
$ cat file_b
This is file A.
$ vim file_b
...  
$ cat file_b
This is file B after the change.
$ cat file_a
This is file B after the change.
```

If you try the same experiment using **cp** instead of **ln** and change a *copy* of the file, the difference between the two utilities will become clearer. Once you change a *copy* of a file, the two files are different:

```bash
$ cat file_c
This is file C.
$ cp file_c file_d
$ cat file_d
This is file C.
$ vim file_d
...  
$ cat file_d
```
This is file D after the change.

$ cat file_c

This is file C.

ls and link counts

You can use `ls` with the `-l` option, followed by the names of the files you want to compare, to see that the status information is the same for two links to the same file and is different for files that are not linked. In the following example, the 2 in the links field (just to the left of `alex`) shows there are two links to `file_a` and `file_b`:

```
$ ls -l file_a file_b file_c file_d
-rw-r--r-- 2 alex pubs 33  May 24 10:52 file_a
-rw-r--r-- 2 alex pubs 33  May 24 10:52 file_b
-rw-r--r-- 1 alex pubs 16  May 24 10:55 file_c
-rw-r--r-- 1 alex pubs 33  May 24 10:57 file_d
```

Although it is easy to guess which files are linked to one another in this example, `ls` does not explicitly tell you.

ls and inodes

Use `ls` with the `-i` option to determine definitively which files are linked. The `-i` option lists the `inode` (page 880) number for each file. An `inode` is the control structure for a file. If two filenames have the same inode number, they share the same control structure and are links to the same file. Conversely, when two filenames have different inode numbers, they are different files. The following example shows that `file_a` and `file_b` have the same inode number and that `file_c` and `file_d` have different inode numbers:

```
$ ls -i file_a file_b file_c file_d
3534 file_a    3534 file_b    5800 file_c    7328 file_d
```

All links to a file are of equal value: The operating system cannot distinguish the order in which multiple links were created. When a file has two links, you can remove either one and still access the file through the remaining link. You can remove the link used to create the file and, as long as one link remains, still access the file through that link.

SYMBOLIC LINKS

In addition to hard links, Linux supports links called `symbolic links`, `soft links`, or `symlinks`. A hard link is a pointer to a file (the directory entry points to the inode), whereas a symbolic link is an `indirect` pointer to a file (the directory entry contains the pathname of the pointed-to file—a pointer to the hard link to the file).
Limitations of hard links

Symbolic links were developed because of the limitations inherent in hard links. You cannot create a hard link to a directory, but you can create a symbolic link to a directory. A symbolic link can point to any file, regardless of where it is located in the file structure, but a hard link to a file must be in the same filesystem as the other hard link(s) to the file.

Often the Linux file hierarchy is composed of several filesystems. Because each filesystem keeps separate control information (that is, separate inode tables) for the files it contains, it is not possible to create hard links between files in different filesystems. When you create links only among files in your own directories, you will not notice these limitations.

One of the big advantages of a symbolic link is that it can point to a nonexistent file. This ability is useful if you need a link to a file that is periodically removed and re-created. A hard link keeps pointing to a "removed" file, which the hard link keeps alive even after a new file is created. A symbolic link always points to the newly created file and does not interfere with deleting the old file. For example, a symbolic link could point to a file that gets checked in and out under a source code control system, a .o file that is re-created by the C compiler each time you run make, or a log file that is periodically archived.

Although they are more general than hard links, symbolic links have some disadvantages. Whereas all hard links to a file have equal status, symbolic links do not have the same status as hard links. When a file has multiple hard links, it is analogous to a person having multiple full legal names, as many married women do. In contrast, symbolic links are analogous to nicknames. Anyone can have one or more nicknames but these nicknames have a lesser status than legal names. The following sections describe some of the peculiarities of symbolic links.

**ln: Creates a Symbolic Link**

Use `ln` with the `--symbolic` (or `-s`) option to create a symbolic link. The following example creates the symbolic link `/tmp/s3` to the file `sum` in Alex's home directory. When you use the `ls -l` command to look at the symbolic link, `ls` displays the name of the link and the name of the file it points to. The first character of the listing is `l` (for link):

```
$ ln --symbolic /home/alex/sum /tmp/s3
$ ls -l /home/alex/sum /tmp/s3
-rw-rw-r--   1 alex alex 38 Jun 12 09:51 /home/alex/sum
lrwxrwxrwx   1 alex alex 14 Jun 12 09:52 /tmp/s3 -> /home/alex/sum
$ cat /tmp/s3
This is sum.
```

The sizes and times of the last modification of the two files are different. Unlike a hard link, a symbolic link to a file does not have the same status information as the file itself.

Similarly you can use `ln` to create a symbolic link to a directory. When you use the `--symbolic` option, `ln` does not care whether the file you are creating a link to is a regular file or a directory.

**tip: Use absolute pathnames with symbolic links**
Symbolic links are literal and are not aware of directories. A link that points to a relative pathname, which includes simple filenames, assumes that the relative pathname is relative to the directory that the link was created in (not the directory the link was created from). In the following example, the link points to the file named `sum` in the `/tmp` directory. Because no such file exists, `cat` gives an error message:

```
$ pwd
/home/alex

$ ln --symbolic sum /tmp/s4

$ ls -l sum /tmp/s4
lrwxrwxrwx  1 alex     alex            3 Jun 12 10:13 /tmp/s4 -> sum
-rw-rw-r--  1 alex     alex           38 Jun 12 09:51 sum

$ cat /tmp/s4

cat: /tmp/s4: No such file or directory
```
optional: cd AND SYMBOLIC LINKS

When you use a symbolic link as an argument to `cd` to change directories, the results can be confusing, particularly if you did not realize that you were using a symbolic link.

If you use `cd` to change to a directory that is represented by a symbolic link, the `pwd` builtin lists the name of the symbolic link. The `pwd` utility (`/bin/pwd`) lists the name of the linked-to directory, not the link, regardless of how you got there:

```
$ ln -s /home/alex/grades /tmp/grades.old
$ pwd
/home/alex
$ cd /tmp/grades.old
$ pwd
/tmp/grades.old
$ /bin/pwd
$home/alex/grades
```

When you change directories back to the parent, you end up in the directory holding the symbolic link:

```
$ cd ..
$ pwd
/tmp
$ /bin/pwd
/tmp
```

`rm`: Removes a Link

When you create a file, there is one hard link to it. You can delete the file or, using Linux terminology, remove the link with the `rm` utility. When you remove the last hard link to a file, you can no longer access the information stored there and the operating system releases for use by other files the space the file occupied on the disk. The space is released even if symbolic links to the file remain. When there is more than one hard link to a file, you can remove a hard link and still access the file from any remaining link. Unlike in DOS and Windows, there is no easy way in Linux to undelete a file once you have removed it. A skilled hacker can sometimes piece the file together with time and effort.
When you remove all the hard links to a file, you will not be able to access the file through a symbolic link. In the following example, `cat` reports that the file `total` does not exist because it is a symbolic link to a file that has been removed:

```
$ ls -l sum
-rw-r--r-- 1 alex pubs 981 May 24 11:05 sum
$ ln -s sum total
$ rm sum
$ cat total
cat: total: No such file or directory
$ ls -l total
lrwxrwxrwx 1 alex pubs 6 May 24 11:09 total -> sum
```

When you remove a file, be sure to remove all symbolic links to it. Remove a symbolic link the same way you remove other files:

```
$ rm total
```
Chapter summary

Linux has a hierarchical, or treelike, file structure that makes it possible to organize files so that you can find them quickly and easily. This file structure contains directory files and ordinary files. Directories contain other files, including other directories; ordinary files generally contain text, programs, or images. The ancestor of all files is the root directory named `/`.

This chapter introduced many important system files and directories, explaining what each does. The section on file types explained the difference between ordinary and directory files and the inodes that hold each. It also covered the use of hard and symbolic links.

Most Linux filesystems support 255-character filenames. Nonetheless, it is a good idea to keep filenames simple and intuitive. Filename extensions can help make filenames more meaningful.

An absolute pathname starts with the root directory and contains all the filenames that trace a path to a given file. Such a pathname starts with a slash representing the root directory and contains additional slashes between the other filenames in the path.

A relative pathname is similar to an absolute pathname but starts the path tracing from the working directory. A simple filename is the last element of a pathname and is a form of a relative pathname.

When you are logged in, you are always associated with a working directory. Your home directory is your working directory from the time you first log in until you use `cd` to change directories.

A Linux filesystem contains many important directories, including `/usr/bin`, which stores most of the Linux utility commands, and `/dev`, which stores device files, many of which represent physical pieces of hardware. An important standard file is `/etc/passwd`; it contains information about users, such as the user ID and full name.

Among the attributes associated with each file are access permissions. They determine who can access the file and the manner in which the file may be accessed. Three groups of user(s) can access the file: the owner, members of a group, and all other users. A regular file can be accessed in three ways: read, write, and execute. The `ls` utility with the `-l` option displays these permissions. For directories, execute access is redefined to mean that the directory can be searched.

The owner of a file or Superuser can use the `chmod` utility to change the access permissions of a file. This utility defines read, write, and execute permissions for the file's owner, the group, and all other users on the system.

A link is a pointer to a file. You can create several links to a single file so that you can share the file with other users or have the file appear in more than one directory. Because only one copy of a file with multiple links exists, changing the file through any one link causes the changes to appear in all the links. Hard links cannot link directories or span filesystems, whereas symbolic links can.

Table 4-2 lists the utilities introduced in this chapter.

Exercises

1. Is each of the following an absolute pathname, a relative pathname, or a simple filename?
   
a. milk_co
b. correspond/business/milk_co
c. /home/alex
d. /home/alex/literature/promo
e. ..
f. letter.0610

2. List the commands you can use to
   
a. Make your home directory the working directory
b. Identify the working directory

3. If your working directory is /home/alex with a subdirectory named literature, give three sets of commands that you can use to create a subdirectory named classics under literature. Also give several sets of commands you can use to remove the classics directory and its contents.

4. The df utility displays all mounted filesystems along with information about each. Use the df utility with the h (humanly readable) option to answer the following questions.
   
a. How many filesystems are on your Linux system?
b. Which filesystem stores your home directory?
c. Assuming that your answer to exercise 4a is two or greater, attempt to create a hard link to a file on another filesystem. What error message do you get? What happens when you attempt to create a symbolic link to the file instead?

5. Suppose that you have a file that is linked to a file owned by another user. What can you do so that changes to the file are no longer shared?

6. You should have read permission for the /etc/passwd file. To answer the following questions, use cat or less to display /etc/passwd. Look at the fields of information in /etc/passwd for the users on your system.
   
a. Which character is used to separate fields in /etc/passwd?
b. How many fields are used to describe each user?
c. How many users are on your system?
d. How many different login shells are in use on your system? (Hint: Look at the last field.)

e. The second field of /etc/passwd stores user passwords in encoded form. If the password field contains an x, your system uses shadow passwords and stores the encoded passwords elsewhere. Does your system use shadow passwords?

7. If /home/jenny/draft and /home/alex/letter are links to the same file and the following sequence of events occurs, what will be the date in the opening of the letter?

a. Alex gives the command vim letter.

b. Jenny gives the command vim draft.

c. Jenny changes the date in the opening of the letter to January 31, 2006, writes the file, and exits from vim.

d. Alex changes the date to February 1, 2006, writes the file, and exits from vim.

8. Suppose that a user belongs to a group that has all permissions on a file named jobs_list, but the user, as the owner of the file, has no permissions. Describe what operations, if any, the user/owner can perform on jobs_list.

Which command can the user/owner give that will grant the user/owner all permissions on the file?

9. Does the root directory have any subdirectories that you cannot search? Does the root directory have any subdirectories that you cannot read? Explain.

10. Assume that you are given the directory structure shown in Figure 4-2 on page 77 and the following directory permissions:

\[
\texttt{d--x--x--- 3 jenny pubs 512 Mar 10 15:16 business}
\]

\[
\texttt{drwxr-xr-x 2 jenny pubs 512 Mar 10 15:16 business/milk_co}
\]

For each category of permissions—owner, group, and other—what happens when you run each of the following commands? Assume that the working directory is the parent of correspond and that the file cheese_co is readable by everyone.

a. cd correspond/business/milk_co

b. ls -l correspond/business

c. cat correspond/business/cheese_co
ADVANCED EXERCISES

11. What is an inode? What happens to the inode when you move a file within a filesystem?

12. What does the .. entry in a directory point to? What does this entry point to in the root (/) directory?

13. How can you create a file named ii? Which techniques do not work, and why do they not work? How can you remove the file named ii?

14. Suppose that the working directory contains a single file named andor. What error message do you get when you run the following command line?

   $ mv andor and/or

Under what circumstances is it possible to run the command without producing an error?

15. The ls -li command displays a filename preceded by the inode number of the file (page 99). Write a command to output inode/filename pairs for the files in the working directory, sorted by inode number. (Hint: Use a pipe.)

16. Do you think that the system administrator has access to a program that can decode user passwords? Why or why not (see exercise 6)?

17. Is it possible to distinguish a file from a hard link to a file? That is, given a filename, can you tell whether it was created using an ln command? Explain.

18. Explain the error messages displayed in the following sequence of commands:

   $ ls -l
   total 1
   drwxrwxr-x  2 alex pubs 1024 Mar  2 17:57 dirtmp

   $ ls dirtmp

   $ rmdir dirtmp
   rmdir: dirtmp: Directory not empty

   $ rm dirtmp/*
   rm: No match.
Chapter 5. The Shell

IN THIS CHAPTER

The Command Line 108
Standard Input and Standard Output 113
Redirection 116
Pipes 122
Running a Program in the Background 125
kill: Aborting a Background Job 127
Filename Generation/Pathname Expansion 127
Builtins 132

This chapter takes a close look at the shell and explains how to use some of its features. For example, it discusses command line syntax and also describes how the shell processes a command line and initiates execution of a program. The chapter also explains how to redirect input to and output from a command, construct pipes and filters on the command line, and run a command in the background. The final section covers filename expansion and explains how you can use this feature in your everyday work.

Except as noted everything in this chapter applies to the Bourne Again (bash) and TC (tcsh) Shells. The exact wording of the shell output differs from shell to shell: What your shell displays may differ slightly from what appears in this book. For shell-specific information, refer to Chapters 8 (bash) and 9 (tcsh). Chapter 11 covers writing and executing bash shell scripts.
The Command Line

The shell executes a program when you give it a command in response to its prompt. For example, when you give the `ls` command, the shell executes the utility program named `ls`. You can cause the shell to execute other types of programs—such as shell scripts, application programs, and programs you have written—in the same way. The line that contains the command, including any arguments, is called the command line. In this book the term command refers to the characters you type on the command line as well as to the program that action invokes.

Syntax

Command line syntax dictates the ordering and separation of the elements on a command line. When you press the RETURN key after entering a command, the shell scans the command line for proper syntax. The syntax for a basic command line is

```
command [arg1] [arg2] ... [argn]
RETURN
```

One or more SPACEs must separate elements on the command line. The command is the name of the command, arg1 through argn are arguments, and RETURN is the keystroke that terminates all command lines. The brackets in the command line syntax indicate that the arguments they enclose are optional. Not all commands require arguments: Some commands do not allow arguments; other commands allow a variable number of arguments; and others require a specific number of arguments. Options, a special kind of argument, are usually preceded by one or two hyphens (also called a dash or minus sign: `-`).

Command Name

Usage message

Some useful Linux command lines consist of only the name of the command without any arguments. For example, `ls` by itself lists the contents of the working directory. Most commands accept one or more arguments. Commands that require arguments typically give a short error message, called a usage message, when you use them without arguments, with incorrect arguments, or with the wrong number of arguments.

Arguments

On the command line each sequence of nonblank characters is called a token or word. An argument is a token, such as a filename, string of text, number, or other object that a command acts on. For example, the argument to a `vim` or `emacs` command is the name of the file you want to edit.

The following command line shows `cp` copying the file named `temp` to `tempcopy`:

```
$ cp temp tempcopy
```

Arguments are numbered starting with the command itself as argument zero. In this example `cp` is argument zero, `temp` is argument one, and `tempcopy` is argument two. The `cp` utility requires two arguments on the command line. (The utility can take more arguments but not fewer; see page 616.) Argument one is the name of an existing file. Argument two is the name of the file that `cp` is creating or overwriting. Here the arguments are not optional; both
arguments must be present for the command to work. When you do not supply the right number or kind of arguments, `cp` displays a usage message. Try typing `cp` and then pressing RETURN.

**Options**

An option is an argument that modifies the effects of a command. You can frequently specify more than one option, modifying the command in several different ways. Options are specific to and interpreted by the program that the command line calls, not the shell.

By convention options are separate arguments that follow the name of the command and usually precede other arguments, such as filenames. Most utilities require you to prefix options with a single hyphen. However, this requirement is specific to the utility and not the shell. GNU program options are frequently preceded by two hyphens in a row. For example, `help` generates a (sometimes extensive) usage message.

Figure 5-1 first shows what happens when you give an `ls` command without any options. By default `ls` lists the contents of the working directory in alphabetical order, vertically sorted in columns. Next the `-r` (reverse order; because this is a GNU utility, you can also use `-reverse`) option causes the `ls` utility to display the list of files in reverse alphabetical order, still sorted in columns. The `-x` option causes `ls` to display the list of files in horizontally sorted rows.

**Combining options**

When you need to use several options, you can usually group multiple single-letter options into one argument that starts with a single hyphen; do not put SPACEs between the options. You cannot combine options that are preceded by two hyphens in this way, however. Specific rules for combining options depend on the program you are running. Figure 5-1 shows both the `-r` and `-x` options with the `ls` utility. Together these options generate a list of filenames in horizontally sorted columns, in reverse alphabetical order. Most utilities allow you to list options in any order; thus `ls -xr` produces the same results as `ls -rx`. The command `ls -x -r` also generates the same list.

**Figure 5-1. Using options**

```
$ ls
alex house mark office personal test
hold jenny names oldstuff temp

$ ls -r

test personal office mark house alex

temp oldstuff names jenny hold

$ ls -x

alex hold house jenny mark names

office oldstuff personal temp test

$ ls -rx
```
tip: Displaying readable file sizes: the \texttt{h} option

Most utilities that report on file sizes specify the size of a file in bytes. Bytes work well when you are dealing with smaller files, but the numbers can be difficult to read when you are working with file sizes that are measured in megabytes or gigabytes. Use the \texttt{h} (or \texttt{human-readable}) option to display file sizes in kilo-, mega-, and gigabytes. Experiment with \texttt{df h} (disk free) and \texttt{ls lh} commands.

Option arguments

Some utilities have options that themselves require arguments. For example, the \texttt{gcc} utility has a \texttt{o} option that must be followed by the name you want to give the executable file that \texttt{gcc} generates. Typically an argument to an option is separated from its option letter by a SPACE:

\begin{verbatim}
$ gcc -o prog prog.c
\end{verbatim}

Arguments that start with a hyphen

Another convention allows utilities to work with arguments, such as filenames, that start with a hyphen. If a file's name is \texttt{l}, the following command is ambiguous:

\begin{verbatim}
$ ls -l
\end{verbatim}

This command could mean a long listing of all files in the working directory or a listing of the file named \texttt{-l}. It is interpreted as the former. You should avoid creating files whose names begin with hyphens. If you do create them, many utilities follow the convention that a \texttt{--} argument (two consecutive hyphens) indicates the end of the options (and the beginning of the arguments). To disambiguate the command, you can type

\begin{verbatim}
$ ls -- -l
\end{verbatim}

You can use an alternative format in which the period refers to the working directory and the slash indicates that the name refers to a file in the working directory:

\begin{verbatim}
$ ls ./-l
\end{verbatim}

Assuming that you are working in the \texttt{/home/alex} directory, the preceding command is functionally equivalent to
$ ls /home/alex/-l

You can give the following command to get a long listing of this file:

$ ls -l -- -l

These are conventions, not hard-and-fast rules, and a number of utilities do not follow them (e.g., find). Following such conventions is a good idea; it makes it much easier for users to work with your program. When you write shell programs that require options, follow the Linux option conventions.

**tip: The `--help` option**

Many utilities display a (sometimes extensive) help message when you call them with an argument of `--help`. All GNU utilities accept this option. An example follows.

$ bzip2 --help

usage: bzip2 [flags and input files in any order]

-h --help               print this message
-d --decompress         force decompression
-z --compress           force compression
-k --keep               keep (don't delete) input files
-f --force              overwrite existing output files
-t --test               test compressed file integrity
-c --stdout             output to standard out
-q --quiet              suppress noncritical error messages
-v --verbose            be verbose (a 2nd -v gives more)

...
CONTROL-W (to erase a word). When the character you entered does not require immediate action, the device driver stores the character in a buffer and waits for additional characters. When you press RETURN, the device driver passes the command line to the shell for processing.

**Parsing the command line**

When the shell processes a command line, it looks at the line as a whole and parses (breaks) it into its component parts (Figure 5-2). Next the shell looks for the name of the command. Usually the name of the command is the first item on the command line after the prompt (argument zero). The shell takes the first characters on the command line up to the first blank (TAB or SPACE) and then looks for a command with that name. The command name (the first token) can be specified on the command line either as a simple filename or as a pathname. For example, you can call the `ls` command in either of the following ways:

```
$ ls
$ /bin/ls
```

*Figure 5-2. Processing the command line*
optional

The shell does not require that the name of the program appear first on the command line. Thus you can structure a command line as follows:

```
$ >bb <aa cat
```

This command runs `cat` with standard input coming from the file named `aa` and standard output going to the file named `bb`. When the shell recognizes the redirect symbols (page 116), it recognizes and processes them and their arguments before finding the name of the program that the command line is calling. This is a properly structured albeit rarely encountered and possibly confusing command line.

Absolute versus relative pathnames

When you give an absolute pathname on the command line or a relative pathname that is not a simple filename (i.e., any pathname that includes at least one slash), the shell looks in the specified directory (`/bin` in the case of the `/bin/ls` command) for a file that has the name `ls` and that you have permission to execute. When you give a simple filename, the shell searches through a list of directories for a filename that matches the specified name and that you have execute permission for. The shell does not look through all directories but only the ones specified by the variable named `PATH`. Refer to page 284 (`bash`) or page 363 (`tcsh`) for more information on `PATH`. Also refer to the discussion of the `which` and `whereis` utilities on page 61.

When it cannot find the executable file, the Bourne Again Shell (`bash`) displays a message such as the following:

```
$ abc
bash: abc: command not found
```

One reason the shell may not be able to find the executable file is that it is not in a directory in your `PATH`. Under `bash` the following command temporarily adds the working directory (`.`) to your `PATH`:

```
$ PATH=$PATH:. 
```

For security reasons, you may not want to add the working directory to `PATH` permanently; see the tip on page 285.

When the shell finds the program but cannot execute it (you do not have execute permission for the file that contains the program), it displays a message similar to

```
$ def
bash: ./def: Permission denied
```

See "`ls l: Displays Permissions`" on page 91 for information on displaying access permissions for a file and
"chmod: Changes Access Permissions" on page 92 for instructions on how to change file access permissions.

**Executing the Command Line**

**Process**

If it finds an executable file with the same name as the command, the shell starts a new process. A *process* is the execution of a command by Linux (page 292). The shell makes each command line argument, including options and the name of the command, available to the called program. While the command is executing, the shell waits for the process to finish. At this point the shell is in an inactive state called *sleep*. When the program finishes execution, it passes its exit status (page 479) to the shell. The shell then returns to an active state (wakes up), issues a prompt, and waits for another command.

**The shell does not process arguments**

Because the shell does not process command line arguments but only hands them to the called program, the shell has no way of knowing whether a particular option or other argument is valid for a given program. Any error or usage messages about options or arguments come from the program itself. Some utilities ignore bad options.
Standard Input and Standard Output

*Standard output* is a place that a program can send information, such as text. The program never "knows" where the information it sends to standard output is going (Figure 5-3). The information can go to a printer, an ordinary file, or the screen.

![Figure 5-3](image)

The command does not know where standard input comes from or where standard output and standard error go

The following sections show that by default the shell directs standard output from a command to the screen and describe how you can cause the shell to redirect this output to another file.

[1] The term *screen* is used throughout this book to mean screen, terminal emulator window, or workstation. *Screen* refers to the device that you see the prompt and messages displayed on.

*Standard input* is a place that a program gets information from. As with standard output the program never "knows" where the information came from. The following sections also explain how to redirect standard input to a command so that it comes from an ordinary file instead of from the keyboard (the default).

In addition to standard input and standard output, a running program normally has a place to send error messages: *standard error*. Refer to page 260 (bash) and page 349 (tcsh) for more information on handling standard error.

**tip: chsh: changes your login shell**

The person who sets up your account determines which shell you will use when you first log in on the system or when you open a terminal emulator window in a GUI environment. You can run any shell you like once you are logged in. Enter the name of the shell you want to use (bash or tcsh) and press RETURN; the next prompt will be that of the new shell. Give an **exit** command to return to the previous shell. Because shells you call in this manner are nested (one runs on top of the other), you will be able to log out only from your original shell. When you have nested several shells, keep giving **exit** commands until you reach your original shell. You will then be able to log out.

Use the **chsh** utility when you want to change your login shell permanently. First give the command **chsh**. Then in response to the prompts enter your password and the absolute pathname of the shell you want to use (/bin/bash or /bin/tcsh). When you change your login shell in this manner using a terminal emulator PAGE under a GUI, subsequent terminal emulator windows will not reflect the change until you log out the system and log back in.

**The Screen as a File**

Chapter 4 introduced ordinary files, directory files, and hard and soft links. Linux has an additional type of file: a *device file*. A device file resides in the Linux file structure, usually in the /dev directory, and represents a peripheral device, such as a terminal emulator window, screen, printer, or disk drive.
The device name that the `who` utility displays after your login name is the filename of your screen. For example, when `who` displays the device name `pts/4`, the pathname of your screen is `/dev/pts/4`. When you work with multiple windows, each window has its own device name. You can also use the `tty` utility to display the name of the device that you give the command from. Although you would not normally have occasion to do so, you can read from and write to this file as though it were a text file. Writing to it displays what you wrote on the screen; reading from it reads what you entered on the keyboard.

**The Keyboard and Screen as Standard Input and Standard Output**

When you first log in, the shell directs standard output of your commands to the device file that represents your screen (Figure 5-4). Directing output in this manner causes it to appear on your screen. The shell also directs standard input to come from the same file, so that your commands receive as input anything you type on your keyboard.

![Figure 5-4. By default, standard input comes from the keyboard and standard output goes to the screen](image)

The `cat` utility provides a good example of the way the keyboard and the screen function as standard input and standard output, respectively. When you use `cat`, it copies a file to standard output. Because the shell directs standard output to the screen, `cat` displays the file on the screen.

Up to this point `cat` has taken its input from the filename (argument) you specified on the command line. When you do not give `cat` an argument (that is, when you give the command `cat` followed immediately by RETURN), `cat` takes its input from standard input. Thus, when called without an argument, `cat` copies standard input to standard output, one line at a time.

To see how `cat` works, type `cat` and press RETURN in response to the shell prompt. Nothing happens. Enter a line of text and press RETURN. The same line appears just under the one you entered. The `cat` utility is working. Because the shell associates `cat`'s standard input with the keyboard and `cat`'s standard output with the screen, when you type a line of text `cat` copies the text from standard input (the keyboard) to standard output (the screen). This exchange is shown in Figure 5-5.

![Figure 5-5. The cat utility copies standard input to standard output](image)
$ cat
This is a line of text.

This is a line of text.

Cat keeps copying lines of text

Cat keeps copying lines of text

until you press CONTROL-D at the beginning

until you press CONTROL-D at the beginning

of a line.

of a line.

CONTROL-D

$
where *command* is any executable program (such as an application program or a utility), *arguments* are optional arguments, and *filename* is the name of the ordinary file the shell redirects the output to.

Figure 5-7 uses `cat` to demonstrate output redirection. This figure contrasts with Figure 5-3 on page 114, where both standard input and standard output are associated with the keyboard and the screen. The input in Figure 5-7 comes from the keyboard. The redirect output symbol on the command line causes the shell to associate `cat`'s standard output with the *sample.txt* file specified on the command line.

After giving the command and typing the text shown in Figure 5-7, the *sample.txt* file contains the text you entered. You can use `cat` with an argument of *sample.txt* to display this file. The next section shows another way to use `cat` to display the file.

**caution: Redirecting output can destroy a file**

Use caution when you redirect output to a file. If the file exists, the shell will overwrite it and destroy its contents. For more information, see the "Redirecting output can destroy a file II" caution on page 120.

Figure 5-7 shows that redirecting the output from `cat` is a handy way to create a file without using an editor. The drawback is that once you enter a line and press RETURN, you cannot edit the text. While you are entering a line, the erase and kill keys work to delete text. This procedure is useful for making short, simple files.

Figure 5-7. `cat` with its output redirected

```bash
$ cat > sample.txt
This text is being entered at the keyboard and
`cat` is copying it to a file.
Press CONTROL-D to indicate the
end of file.
CONTROL-D
$
```

Figure 5-8. Using `cat` to catenate files

```bash
$ cat stationery
```
2,000 sheets letterhead ordered: 10/7/05

$ cat tape

1 box masking tape ordered: 10/14/05
5 boxes filament tape ordered: 10/28/05

$ cat pens

12 doz. black pens ordered: 10/4/05

$ cat stationery tape pens > supply_orders
$ cat supply_orders

2,000 sheets letterhead ordered: 10/7/05
1 box masking tape ordered: 10/14/05
5 boxes filament tape ordered: 10/28/05
12 doz. black pens ordered: 10/4/05

Figure 5-8 shows how to use cat and the redirect output symbol to catenate (join one after the other; the derivation of the name of the cat utility) several files into one larger file. The first three commands display the contents of three files: stationery, tape, and pens. The next command shows cat with three filenames as arguments. When you call it with more than one filename, cat copies the files, one at a time, to standard output. In this case standard output is redirected to the file supply_orders. The final cat command shows that supply_orders contains the contents of all three files.

Redirecting Standard Input

Just as you can redirect standard output, so you can redirect standard input. The redirect input symbol (<) instructs the shell to redirect a command's input to come from the specified file instead of from the keyboard (Figure 5-9). The format of a command line that redirects input is

command [arguments] < filename

Figure 5-9. Redirecting standard input
where *command* is any executable program (such as an application program or a utility), *arguments* are optional arguments, and *filename* is the name of the ordinary file the shell redirects the input from.

Figure 5-10 shows **cat** with its input redirected from the **supply_orders** file that was created in Figure 5-8 and standard output going to the screen. This setup causes **cat** to display the sample file on the screen. The system automatically supplies an EOF (end of file) signal at the end of an ordinary file.

![Diagram of file redirection](image)

$ cat < supply_orders

2,000 sheets letterhead ordered:  10/7/05
1 box masking tape ordered:     10/14/05
5 boxes filament tape ordered:  10/28/05
12 doz. black pens ordered:     10/4/05

Utilities that take input from a file or standard input

Giving a **cat** command with input redirected from a file yields the same result as giving a **cat** command with the filename as an argument. The **cat** utility is a member of a class of Linux utilities that function in this manner. Other members of this class of utilities include **lpr, sort, and grep**. These utilities first examine the command line that you use to call them. If you include a filename on the command line, the utility takes its input from the file you specify. If you do not specify a filename, the utility takes its input from standard input. It is the utility or program—not the shell or operating system—that functions in this manner.

**noclobber**: Avoids Overwriting Files

The shell provides a feature called **noclobber** that stops you from inadvertently overwriting an existing file using redirection. When you enable this feature by setting the **noclobber** variable and then attempt to redirect output to an existing file, the shell displays an error message and does not execute the command. If the preceding examples
result in one of the following messages, the **noclobber** feature has been set. The following examples set **noclobber**, attempt to redirect the output from `echo` into an existing file, and then unset **noclobber** under `bash` and `tcsh`:

```
bash    $ set -o noclobber
         $ echo "hi there" > tmp
           bash: tmp: Cannot overwrite existing file

         $ set +o noclobber
         $ echo "hi there" > tmp

         $ set -o noclobber
         $ echo "hi there" > tmp

         $

tcsh     tcsh $ set noclobber
         tcsh $ echo "hi there" > tmp
          tmp: File exists.
         tcsh $ unset noclobber
         tcsh $ echo "hi there" > tmp

         $
```

You can override **noclobber** by putting a pipe symbol (**tcsh** uses an exclamation point) after the symbol you use for redirecting output (>!).

In the following example, the user first creates a file named `a` by redirecting the output of `date` to the file. Next the user sets the **noclobber** variable and tries redirecting output to `a` again. The shell returns an error message. Then the user tries the same thing but using a pipe symbol after the redirect symbol. This time the shell allows the user to overwrite the file. Finally, the user unsets **noclobber** (using a plus sign in place of the hyphen) and verifies that it is no longer set.

```
$ date > a
$ set -o noclobber
$ date > a
bash: a: Cannot overwrite existing file

$ date >| a
  $ set +o noclobber
  $ date > a
```

For more information on using **noclobber** under `tcsh`, refer to page 367.

**caution: Redirecting output can destroy a file**

Depending on which shell you are using and how your environment has been set up, a command such as the following may give you undesired results:
$ cat orange pear > orange

    cat: orange: input file is output file

Although `cat` displays an error message, the shell goes ahead and destroys the contents of the existing `orange` file. The new `orange` file will have the same contents as `pear` because the first action the shell takes when it sees the redirection symbol (`>` is to remove the contents of the original `orange` file. If you want to catenate two files into one, use `cat` to put the two files into a temporary file and then use `mv` to rename this third file:

    $ cat orange pear > temp
    $ mv temp orange

What happens in the next example can be even worse. The user giving the command wants to search through files `a`, `b`, and `c` for the word `apple` and redirect the output from `grep` to the file `a.output`. Unfortunately the user enters the filename as `a output`, omitting the period and inserting a SPACE in its place:

    $ grep apple a b c > a output

    grep: output: No such file or directory

The shell obediently removes the contents of `a` and then calls `grep`. The error message may take a moment to appear, giving you a sense that the command is running correctly. Even after you see the error message, it may take a while to realize that you destroyed the contents of `a`.

### Appending Standard Output to a File

The *append output symbol* (`>>`) causes the shell to add new information to the end of a file, leaving any existing information intact. This symbol provides a convenient way of catenating two files into one. The following commands demonstrate the action of the append output symbol. The second command accomplishes the catenation described in the preceding caution box:

    $ cat orange

    this is orange

    $ cat pear >> orange
    $ cat orange

    this is orange

    this is pear
You first see the contents of the **orange** file. Next the contents of the **pear** file is added to the end of (catenated with) the **orange** file. The final **cat** shows the result.

**caution: Do not trust noclobber**

Appending output is simpler than the two-step procedure described in the preceding caution box but you must be careful to include both greater than signs. If you accidentally use only one and the **noclobber** feature is not on, you will overwrite the **orange** file. Even if you have the **noclobber** feature turned on, it is a good idea to keep backup copies of files you are manipulating in these ways in case you make a mistake.

Although it protects you from making an erroneous redirection, **noclobber** does not stop you from overwriting an existing file using **cp** or **mv**. These utilities include the **i** (interactive) option that helps protect you from this type of mistake by verifying your intentions when you try to overwrite a file. For more information, see the "**cp can destroy a file**" tip on page 46.

The next example shows how to create a file that contains the date and time (the output from **date**), followed by a list of who is logged in (the output from **who**). The first line in **Figure 5-11** redirects the output from **date** to the file named **whoson**. Then **cat** displays the file. Next the example appends the output from **who** to the **whoson** file. Finally **cat** displays the file containing the output of both utilities.

**Figure 5-11. Redirecting and appending output**

```
$ date > whoson
$ cat whoson
Thu Mar 24 14:31:18 PST 2005

$ who >> whoson
$ cat whoson
Thu Mar 24 14:31:18 PST 2005

root       console      Mar 24 05:00(:0)
alex       pts/4        Mar 24 12:23(:0.0)
alex       pts/5        Mar 24 12:33(:0.0)
jenny      pts/7        Mar 23 08:45 (bravo.example.com)
```

**/dev/null: Making Data Disappear**

The **/dev/null** device is a **data sink**, commonly referred to as a **bit bucket**. You can redirect output that you do not want to keep or see to **/dev/null**. The output disappears without a trace:

```
$ echo "hi there" > /dev/null
```

$
When you read from `/dev/null`, you get a null string. Give the following `cat` command to truncate a file named `messages` to zero length while preserving the ownership and permissions of the file:

```
$ ls -l messages
-rw-r--r--   1 alex pubs 25315 Oct 24 10:55 messages
$ cat /dev/null > messages
$ ls -l messages
-rw-r--r--   1 alex pubs 0 Oct 24 11:02 messages
```

Pipes

The shell uses a pipe to connect standard output of one command directly to standard input of another command. A pipe (sometimes referred to as a pipeline) has the same effect as redirecting standard output of one command to a file and then using that file as standard input to another command. A pipe does away with separate commands and the intermediate file. The symbol for a pipe is a vertical bar (`|`). The syntax of a command line using a pipe is

```
command_a [arguments] | command_b [arguments]
```

The preceding command line uses a pipe to generate the same result as the following group of command lines:

```
command_a [arguments] > temp
command_b [arguments] < temp
rmdir temp
```

In the preceding sequence of commands, the first line redirects standard output from `command_a` to an intermediate file named `temp`. The second line redirects standard input for `command_b` to come from `temp`. The final line deletes `temp`. The command using a pipe is not only easier to type, but is generally more efficient because it does not create a temporary file.

`tr`

You can use a pipe with any of the Linux utilities that accept input either from a file specified on the command line or from standard input. You can also use pipes with commands that accept input only from standard input. For example, the `tr` (translate) utility (page 804) takes its input from standard input only. In its simplest usage `tr` has the following format:

```
tr string1 string2
```

The `tr` utility accepts input from standard input and looks for characters that match one of the characters in `string1`. Upon finding a match, `tr` translates the matched character in `string1` to the corresponding character in `string2`. (The first character in `string1` translates into the first character in `string2`, and so forth.) The `tr` utility sends its output to standard output. In both of the following examples, `tr` displays the contents of the `abstract` file with the letters `a`, `b`,
and \( c \) translated into \( A, B, \) and \( C, \) respectively:

\[
\begin{align*}
\texttt{\$ cat abstract | tr abc ABC} \\
\texttt{\$ tr abc ABC < abstract}
\end{align*}
\]

The **TR** utility does not change the contents of the original file; it cannot change the original file because it does not "know" the source of its input.

**lpr**

The **lpr** (line printer) utility also accepts input from either a file or standard input. When you type the name of a file following **lpr** on the command line, it places that file in the print queue. When you do not specify a filename on the command line, **lpr** takes input from standard input. This feature enables you to use a pipe to redirect input to **lpr**. The first set of commands in Figure 5-12 shows how you can use **ls** and **lpr** with an intermediate file (**temp**) to send a list of the files in the working directory to the printer. If the **temp** file exists, the first command overwrites its contents. The second set of commands sends the same list (with the exception of **temp**) to the printer using a pipe.

The commands in Figure 5-13 redirect the output from the **who** utility to **temp** and then display this file in sorted order. The **sort** utility (page 50) takes its input from the file specified on the command line or, when a file is not specified, from standard input and sends its output to standard output. The **sort** command line in Figure 5-13 takes its input from standard input, which is redirected (<) to come from **temp**. The output that **sort** sends to the screen lists the users in sorted (alphabetical) order.

Because **sort** can take its input from standard input or from a filename on the command line, omitting the < symbol from Figure 5-13 yields the same result.

**Figure 5-12. A pipe**

\[
\begin{align*}
\texttt{\$ ls > temp} \\
\texttt{\$ lpr temp} \\
\texttt{\$ rm temp}
\end{align*}
\]

or

\[
\begin{align*}
\texttt{\$ ls | lpr}
\end{align*}
\]

**Figure 5-13. Using a temporary file to store intermediate results**

\[
\begin{align*}
\texttt{\$ who > temp} \\
\texttt{\$ sort < temp}
\end{align*}
\]

\[
\begin{align*}
\text{alex} & \quad \text{pts/4} & \quad \text{Mar 24 12:23} \\
\text{alex} & \quad \text{pts/5} & \quad \text{Mar 24 12:33}
\end{align*}
\]
Figure 5-14 achieves the same result without creating the temp file. Using a pipe the shell redirects the output from who to the input of sort. The sort utility takes input from standard input because no filename follows it on the command line.

When many people are using the system and you want information about only one of them, you can send the output from who to grep (page 48) using a pipe. The grep utility displays the line containing the string you specify in the following example:

```
$ who | grep 'root'
```

Another way of handling output that is too long to fit on the screen, such as a list of files in a crowded directory, is to use a pipe to send the output through less or more (both on page 45).

```
$ ls | less
```

The less utility displays text one screen at a time. To view another screen, press the SPACE bar. To view one more line, press RETURN. Press h for help and q to quit.

Filters

A filter is a command that processes an input stream of data to produce an output stream of data. A command line that includes a filter uses a pipe to connect standard output of one command to the filter's standard input. Another pipe connects the filter's standard output to standard input of another command. Not all utilities can be used as filters.

In the following example, sort is a filter, taking standard input from standard output of who and using a pipe to redirect standard output to standard input of lpr. This command line sends the sorted output of who to the printer:

```
$ who | sort | lpr
```

The preceding example demonstrates the power of the shell combined with the versatility of Linux utilities. The three utilities who, sort, and lpr were not specifically designed to work with each other, but they all use standard input and standard output in the conventional way. By using the shell to handle input and output, you can piece standard utilities together on the command line to achieve the results you want.
The **tee** utility copies its standard input both to a file and to standard output. The utility is aptly named: It takes a single input and sends the output in two directions. In Figure 5-15 the output of **who** is sent via a pipe to standard input of **tee**. The **tee** utility saves a copy of standard input in a file named **who.out** and also sends a copy to standard output. Standard output of **tee** goes via a pipe to standard input of **grep**, which displays lines containing the string **root**.
Running a Program in the Background

Foreground

In all the examples so far in this book, commands were run in the foreground. When you run a command in the foreground, the shell waits for it to finish before giving you another prompt and allowing you to continue. When you run a command in the background, you do not have to wait for the command to finish before you start running another command.

Jobs

A job is a series of one or more commands that can be connected by pipes. You can have only one foreground job in a window or on a screen, but you can have many background jobs. By running more than one job at a time, you are using one of Linux's important features: multitasking. Running a command in the background can be useful when the command will run for a long time and does not need supervision. It leaves the screen free so that you can use it for other work. Of course, when you are using a GUI, you can open another window to run another job.

Job number, PID number

To run a command in the background, type an ampersand (&) just before the RETURN that ends the command line. The shell assigns a small number to the job and displays this job number between brackets. Following the job number, the shell displays the process identification (PID) number—a larger number assigned by the operating system. Each of these numbers identifies the command running in the background. Then the shell displays another prompt and you can enter another command. When the background job finishes running, the shell displays a message giving both the job number and the command line used to run the command.

Figure 5-15. Using tee

```
$ who | tee who.out | grep root
root       console      Mar 24 05:00
$ cat who.out
root       console      Mar 24 05:00
alex       pts/4        Mar 24 12:23
alex       pts/5        Mar 24 12:33
jenny      pts/7        Mar 23 08:45
```

The following examples use the Bourne Again Shell. The TC Shell produces almost identical results. The next example runs in the background and sends its output through a pipe to lpr, which sends it to the printer.

```
$ ls -l | lpr &
[1] 22092
```
The [1] following the command line indicates that the shell has assigned job number 1 to this job. The 22092 is the PID number of the first command in the job. (The TC Shell shows PID numbers for all commands in the job.) When this background job completes execution, you see the message

```
[1]+ Done          ls -l | lpr
```

(In place of `ls l`, the shell may display something similar to `ls `color/tty` l`. This difference is due to the fact that `ls` is aliased [page 312] to `ls `color/tty`.)

### Moving a Job from the Foreground to the Background

**CONTROL-Z**

You can suspend a foreground job (stop it from running) by pressing the suspend key, usually CONTROL-Z. The shell then stops the process and disconnects standard input from the keyboard. You can put a suspended job in the background and restart it by using the `bg` command followed by the job number. You do not need to use the job number when there is only one stopped job.

Only the foreground job can take input from the keyboard. To connect the keyboard to a program running in the background, you must bring it into the foreground. Type `fg` without any arguments when only one job is in the background. When more than one job is in the background, type `fg`, or a percent sign (%), followed by the number of the job you want to bring into the foreground. The shell displays the command you used to start the job (`promptme` in the following example), and you can enter any input the program requires to continue:

```
bash $ fg 1
promptme
```

Redirect the output of a job you run in the background to keep it from interfering with whatever you are doing on the screen. Refer to "Separating and Grouping Commands" on page 267 for more detail about background tasks.

**kill: Aborting A Background Job**

The interrupt key (usually CONTROL-C) cannot abort a process you are running in the background; you must use `kill` (page 693) for this purpose. Follow `kill` on the command line with either the PID number of the process you want to abort or a percent sign (%) followed by the job number.

### Determining a PID number with ps

If you forget the PID number, you can use the `ps` (process status) utility (page 293) to display it. Using the TC Shell, the following example runs a `tail --outfile` command (the `--` option causes `tail` to watch `outfile` and display new lines as they are written to the file) as a background job, uses `ps` to display the PID number of the process, and aborts the job with `kill`. The same commands work under `bash`. So that it does not interfere with anything on the
screen, the message saying that the job is terminated does not appear until you press RETURN after the RETURN that ends the kill command:

```
tcsh $ tail -f outfile &
[1] 22170

tcsh $ ps | grep tail
22170 pts/7 00:00:00 tail

tcsh $ kill 22170

tcsh $ RETURN

[1] Terminated tail -f outfile

tcsh $
```

If you forget the job number, you can use the jobs command to display a list of job numbers. The next example is similar to the previous one but uses the job number instead of the PID number to kill the job:

```
tcsh $ tail -f outfile &
[1] 3339

tcsh $ bigjob &
[2] 3340

tcsh $ jobs
[1] + Running tail -f outfile
[2] - Running bigjob

tcsh $ kill %1

Terminated tail -f outfile

tcsh $
```
Filename Generation/Pathname Expansion

Wildcards, globbing

When you give the shell abbreviated filenames that contain special characters, also called *metacharacters*, the shell can generate filenames that match the names of existing files. These special characters are also referred to as *wildcards* because they act as the jokers do in a deck of cards. When one of these characters appears in an argument on the command line, the shell expands that argument in sorted order into a list of filenames and passes the list to the program that the command line calls. Filenames that contain these special characters are called *ambiguous file references* because they do not refer to any one specific file. The process that the shell performs on these filenames is called *pathname expansion* or *globbing*.

Ambiguous file references refer to a group of files with similar names quickly, saving you the effort of typing the names individually. They can also help you find a file whose name you do not remember in its entirety. If no filename matches the ambiguous file reference, the shell generally passes the unexpanded reference—special characters and all—to the command.

**The ? Special Character**

The question mark (?) is a special character that causes the shell to generate filenames. It matches any single character in the name of an existing file. The following command uses this special character in an argument to the *lpr* utility:

```
$ lpr memo?
```

The shell expands the `memo?` argument and generates a list of files in the working directory that have names composed of `memo` followed by any single character. The shell then passes this list to *lpr*. The *lpr* utility never "knows" that the shell generated the filenames it was called with. If no filename matches the ambiguous file reference, the shell passes the string itself (`memo?`) to *lpr* or, if it is set up to do so, passes a null string (see *nullglob*, page 322).

The following example uses `ls` first to display the names of all files in the working directory and then to display the filenames that `memo?` matches:

```
$ ls
mem  mem12  memo9  memoalex  newmemo5
memo  memo5  memoa  memos
$ ls memo?
mem05  memo9  memoa  memos
```

The `memo?` ambiguous file reference does not match `mem, memo, memo12, memoalex`, or `newmemo5`. You can also use a question mark in the middle of an ambiguous file reference:
To practice generating filenames, you can use `echo` and `ls`. The `echo` utility displays the arguments that the shell passes to it:

```bash
$ echo may?report
may.report may4report may_report mayqreport
```

To practice generating filenames, you can use `echo` and `ls`. The `echo` utility displays the arguments that the shell passes to it:

```bash
$ echo may?report
may.report may4report may_report mayqreport
```

The shell first expands the ambiguous file reference into a list of all files in the working directory that match the string `may?report` and then passes this list to `echo`, as though you had entered the list of filenames as arguments to `echo`. Next `echo` displays the list of filenames.

A question mark does not match a leading period (one that indicates an invisible filename; see page 80). When you want to match filenames that begin with a period, you must explicitly include the period in the ambiguous file reference.

**The * Special Character**

The asterisk (`*`) performs a function similar to that of the question mark but matches any number of characters, including zero characters, in a filename. The following example shows all of the files in the working directory and then shows three commands that display all the filenames that begin with the string `memo`, end with the string `mo`, and contain the string `alx`:

```bash
$ ls
amemo memo memoalx.0620 memosally user.memo
mem memo.0612 memoalx.keep sallymemo
memalx memoa memorandum typescript
```

```bash
$ echo memo*
mem memo.0612 memoa memoalx.0620 memoalx.keep memorandum memosally
```

```bash
$ echo *mo
amemo memo sallymemo user.memo
```

```bash
$ echo *alx*
```
The ambiguous file reference `memo*` does not match `amemo`, `mem`, `sallymemo`, or `user.memo`. Like the question mark, an asterisk does not match a leading period in a filename.

The `a` option causes `ls` to display invisible filenames. The command `echo *` does not display `.` (the working directory), `..` (the parent of the working directory), `aaa`, or `.profile`. In contrast, the command `echo ..*` displays only those four names:

```
$ ls
aaa memo.sally sally.0612 thurs
memo.0612 report saturday
$ ls -a
. .aaa aaa memo.sally sally.0612 thurs
.. .profile memo.0612 report saturday
$ echo *
aaa memo.0612 memo.sally report sally.0612 saturday thurs
$ echo ..*
. .aaa .profile
```

In the following example `.p*` does not match `memo.0612`, `private`, `reminder`, or `report`. Next the `ls .*` command causes `ls` to list `.private` and `.profile` in addition to the contents of the . directory (the working directory) and the .. directory (the parent of the working directory). When called with the same argument, `echo` displays the names of files (including directories) in the working directory that begin with a dot (.), but not the contents of directories.

```
$ ls -a
. .private memo.0612 reminder
.. .profile private report
$ echo .p*
.private .profile
$ ls .*
.private .profile
```
You can take advantage of ambiguous file references when you establish conventions for naming files. For example, when you end all text filenames with `.txt`, you can reference that group of files with `*.txt`. The next command uses this convention to send all the text files in the working directory to the printer. The ampersand causes `lpr` to run in the background.

```
$ lpr *.txt &
```

**The [] Special Characters**

A pair of brackets surrounding a list of characters causes the shell to match filenames containing the individual characters. Whereas `memo?` matches `memo` followed by any character, `memo[17a]` is more restrictive, and matches only `memo1`, `memo7`, and `memoa`. The brackets define a `character class` that includes all the characters within the brackets. (GNU calls this a `character list`; a GNU `character class` is something different.) The shell expands an argument that includes a character-class definition, by substituting each member of the character class, `one at a time`, in place of the brackets and their contents. The shell then passes the list of matching filenames to the program it is calling.

Each character-class definition can replace only a single character within a filename. The brackets and their contents are like a question mark that substitutes only the members of the character class.

The first of the following commands lists the names of all the files in the working directory that begin with `a`, `e`, `i`, `o`, or `u`. The second command displays the contents of the files named `page2.txt`, `page4.txt`, `page6.txt`, and `page8.txt`.

```
$ echo [aeiou]*
...

$ less page[2468].txt
...
```
A hyphen within brackets defines a range of characters within a character-class definition. For example, [6:9] represents [6789], [a–z] represents all lowercase letters in English, and [a–zA–Z] represents all letters, both uppercase and lowercase, in English.

The following command lines show three ways to print the files named part0, part1, part2, part3, and part5. Each of these command lines causes the shell to call lpr with five filenames:

$ lpr part0 part1 part2 part3 part5

$ lpr part[01235]

$ lpr part[0-35]

The first command line explicitly specifies the five filenames. The second and third command lines use ambiguous file references, incorporating character-class definitions. The shell expands the argument on the second command line to include all files that have names beginning with part and ending with any of the characters in the character class. The character class is explicitly defined as 0, 1, 2, 3, and 5. The third command line also uses a character-class definition but defines the character class to be all characters in the range 03 plus 5.

The following command line prints 39 files, part0 through part38:

$ lpr part[0-9] part[12][0-9] part3[0-8]

The next two examples list the names of some of the files in the working directory. The first lists the files whose names start with a through m. The second lists files whose names end with x, y, or z.

$ echo [a-m]*

... 

$ echo *[x-z]

...
optional

When an exclamation point (!) or a caret (^) immediately follows the opening bracket ([) that defines a character class, the string enclosed by the brackets matches any character not between the brackets. Thus [^ab] matches any filename that does not begin with a or b.

The following examples show that *[^ab] matches filenames that do not end with the letters a or b and that [b-d]* matches filenames that begin with b, c, or d.

$ ls
aa ab ac ad ba bb bc bd cc dd

$ ls *[^ab]
ac ad bc bd cc ddcc dd

$ ls [b-d]*
ba bb bc bd cc dd

You can match a hyphen (-) or a closing bracket (]) by placing it immediately before the final closing bracket.

The next example demonstrates that the ls utility cannot interpret ambiguous file references. First ls is called with an argument of ?old. The shell expands ?old into a matching filename, hold, and passes that name to ls. The second command is the same as the first, except the ? is quoted (refer to "Special Characters" on page 42). The shell does not recognize this question mark as a special character and passes it on to ls. The ls utility generates an error message saying that it cannot find a file named ?old (because there is no file named ?old).

$ ls ?old

hold

$ ls \?old

ls: ?old: No such file or directory

Like most utilities and programs, ls cannot interpret ambiguous file references; that work is left to the shell.

tip: The shell expands ambiguous file references

The shell does the expansion when it processes an ambiguous file reference, not the program that the shell runs. In the examples in this section, the utilities (ls, cat, echo, lpr) never see the ambiguous file references. The shell expands the ambiguous file references and passes a list of ordinary filenames to the utility. In the previous examples, echo shows this to be true because it simply displays its arguments; it never displays the ambiguous file reference.
Builtins

A builtin is a utility (also called a command) that is built into a shell. Each of the shells has its own set of builtins. When it runs a builtin, the shell does not fork a new process. Consequently builtins run more quickly and can affect the environment of the current shell. Because builtins are used in the same way as utilities, you will not typically be aware of whether a utility is built into the shell or is a stand-alone utility.

The echo utility is a shell builtin. The shell always executes a shell builtin before trying to find a command or utility with the same name. See page 487 for an in-depth discussion of builtin commands, page 500 for a list of bash builtins, and page 377 for a list of tcsh builtins.

Listing bash builtins

To get a complete list of bash builtins, give the command info bash builtin. To display a page with more information on each builtin, move the cursor to one of the lines listing a builtin command and press RETURN. Alternatively, after typing info bash, give the command /builtin to search the bash documentation for the string builtin. The cursor will rest on the word Builtin in a menu; press RETURN to display the builtins menu.

Because bash was written by GNU, the info page has better information than does the man page. If you want to read about builtins in the man page, give the command man bash and then search for the section on builtins with the command /^SHELL BUILTIN COMMANDS (search for a line that begins with SHELL . . .).

Listing tcsh builtins

For tcsh, give the command man tcsh to display the tcsh man page and then search for the second occurrence of Builtin commands with the following two commands: /Builtin commands (search for the string) and n (search for the next occurrence of the string).
Chapter Summary

The shell is the Linux command interpreter. It scans the command line for proper syntax, picking out the command name and any arguments. The first argument is argument one, the second is argument two, and so on. The name of the command itself is argument zero. Many programs use options to modify the effects of a command. Most Linux utilities identify an option by its leading one or two hyphens.

When you give it a command, the shell tries to find an executable program with the same name as the command. When it does, the shell executes the program. When it does not, the shell tells you that it cannot find or execute the program. If the command is a simple filename, the shell searches the directories given in the variable PATH in an attempt to locate the command.

When it executes a command, the shell assigns one file to the command's standard input and another file to its standard output. By default the shell causes a command's standard input to come from the keyboard and its standard output to go to the screen. You can instruct the shell to redirect a command's standard input from or standard output to any file or device. You can also connect standard output of one command to standard input of another command using a pipe. A filter is a command that reads its standard input from standard output of one command and writes its standard output to standard input of another command.

When a command runs in the foreground, the shell waits for it to finish before it displays a prompt and allows you to continue. When you put an ampersand (&) at the end of a command line, the shell executes the command in the background and displays another prompt immediately. Run slow commands in the background when you want to enter other commands at the shell prompt. The jobs builtin displays a list of jobs and includes the job number of each.

The shell interprets special characters on a command line to generate filenames. A question mark represents any single character, and an asterisk represents zero or more characters. A single character may also be represented by a character class: a list of characters within brackets. A reference that uses special characters (wildcards) to abbreviate a list of one or more filenames is called an ambiguous file reference.

A builtin is a utility that is built into a shell. Each shell has its own set of builtins. When it runs a builtin, the shell does not fork a new process. Consequently builtins run more quickly and can affect the environment of the current shell.

Utilities and Builtins Introduced in This Chapter

Table 5-1 lists the utilities introduced in this chapter.

<table>
<thead>
<tr>
<th>Utility</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tr</code></td>
<td>Maps one string of characters into another (page 122)</td>
</tr>
<tr>
<td><code>Tee</code></td>
<td>Sends standard input to both a file and standard output (page 125)</td>
</tr>
<tr>
<td><code>Bg</code></td>
<td>Moves a process into the background (page 126)</td>
</tr>
<tr>
<td><code>Fg</code></td>
<td>Moves a process into the foreground (page 126)</td>
</tr>
<tr>
<td><code>Jobs</code></td>
<td>Displays a list of currently running jobs (page 127)</td>
</tr>
</tbody>
</table>
Exercises

1: What does the shell ordinarily do while a command is executing? What should you do if you do not want to wait for a command to finish before running another command?

2: Using `sort` as a filter, rewrite the following sequence of commands:

```
$ sort list > temp
$ lpr temp
$ rm temp
```

3: What is a PID number? Why are these numbers useful when you run processes in the background? Which utility displays the PID numbers of the commands you are running?

4: Assume that the following files are in the working directory:

```
$ ls
intro notesb ref2 section1 section3 section4b
notesa ref1 ref3 section2 section4a sentrev
```

Give commands for each of the following, using wildcards to express filenames with as few characters as possible.

   a. List all files that begin with `section`.
   
   b. List the `section1`, `section2`, and `section3` files only.
   
   c. List the `intro` file only.
   
   d. List the `section1`, `section3`, `ref1`, and `ref3` files.

5: Refer to the documentation of utilities in Part V or the `man` pages to determine which commands will

   a. Output the number of lines in the standard input that contain the `word a` or `A`.
   
   b. Output only the names of the files in the working directory that contain the pattern `$`. 
   
   c. List the files in the working directory in their reverse alphabetical order.
d. Send a list of files in the working directory to the printer, sorted by size.

6: Give a command to

a. Redirect the standard output from a `sort` command into a file named `phone_list`. Assume that the input file is named `numbers`.

b. Translate all occurrences of the characters `[` and `{` to the character `,` and all occurrences of the characters `]` and `}` to the character `)` in the file `permdemos.c`. (Hint: Refer to `tr` on page 804.)

c. Create a file named `book` that contains the contents of two other files: `part1` and `part2`.

7: The `lpr` and `sort` utilities accept input either from a file named on the command line or from standard input.

   a. Name two other utilities that function in a similar manner.

   b. Name a utility that accepts its input only from standard input.

8: Give an example of a command that uses `grep`

   a. With both input and output redirected.

   b. With only input redirected.

   c. With only output redirected.

   d. Within a pipe.

   In which of the preceding is `grep` used as a filter?

9: Explain the following error message. What filenames would a subsequent `ls` display?

   ```
   $ ls
   abc  abd abe abf abg abh
   $ rm abc ab*
   rm: cannot remove 'abc': No such file or directory
   ```
Advanced Exercises

10. When you use the redirect output symbol (>) with a command, the shell creates the output file immediately, before the command is executed. Demonstrate that this is true.

11. In experimenting with shell variables, Alex accidentally deletes his PATH variable. He decides that he does not need the PATH variable. Discuss some of the problems he may soon encounter and explain the reasons for these problems. How could he easily return PATH to its original value?

12. Assume that your permissions allow you to write to a file but not to delete it.
   a. Give a command to empty the file without invoking an editor.
   b. Explain how you might have permission to modify a file that you cannot delete.

13. If you accidentally create a filename that contains a nonprinting character, such as a CONTROL character, how can you rename the file?

14. Why does the noclobber variable not protect you from overwriting an existing file with cp or mv?

15. Why do command names and filenames usually not have embedded SPACEs? How would you create a filename containing a SPACE? How would you remove it? (This is a thought exercise, not recommended practice. If you want to experiment, create and work in a directory that contains only your experimental file.)

16. Create a file named answer and give the following command:

   $ > answers.0102 < answers cat

   Explain what the command does and why. What is a more conventional way of expressing this command?
Chapter 6. The vim Editor

IN THIS CHAPTER

Tutorial: Creating and Editing a File with vim 141
Introduction to vim Features 148
Online Help 149
Command Mode: Moving the Cursor 154
Input Mode 158
Command Mode: Deleting and Changing Text 160
Searching and Substituting 164
Yank, Put, and Delete Commands 171
The General-Purpose Buffer 171
Reading and Writing Files 174
The .vimrc Startup File 176

This chapter begins with a history and description of vi, the original, powerful, sometimes cryptic, interactive, visually oriented text editor. The chapter continues with a tutorial that explains how to use vim (vi improved vi clone supplied with or available for most Linux distributions) to create and edit a file. Much of the tutorial and the balance of the chapter apply to vi and other vi clones. Following the tutorial, the chapter delves into the details of many vim commands and explains how to use parameters to customize vim to meet your needs. It concludes with a quick reference/summary of vim commands. The vim home page is www.vim.org.
History

Before vi was developed, the standard UNIX system editor was ed (still available on most Linux systems), a line-oriented editor that made it difficult to see the context of your editing. Next came ex, a superset of ed. The most notable advantage that ex has over ed is a display-editing facility that allows you to work with a full screen of text instead of just a line. While using ex, you can bring up the display-editing facility by giving a vi (Visual mode) command. People used this display-editing facility so extensively that the developers of ex made it possible to start the editor with the display-editing facility already running, without having to start ex and then give a vi command. Appropriately they named the program vi. You can call the Visual mode from ex, and you can go back to ex while you are using vi. Start by running ex; give a vi command to switch to Visual mode, and give a Q command while in Visual mode to use ex. Give a quit command to exit from ex.

[1] The ex program is usually a link to vi, which is a version of vim on some systems.

vi clones

Linux offers a number of versions, or clones, of vi. The most popular vi clones found on Linux are elvis (elvis.the-little-red-haired-girl.org), nvi (an implementation of the original vi editor, www.bostic.com/vi), vile (dickey.his.com/vile/vile.html), and vim (www.vim.org). Each clone offers additional features beyond those provided with the original vi.

The examples in this book are based on vim. Several Linux distributions support multiple versions of vim. For example, Red Hat provides /bin/vi, a minimal build of vim that is compact and faster to load but offers fewer features, and /usr/bin/vim, a full-featured version of vim.

If you use one of the clones other than vim, or vi itself, you may notice slight differences from the examples presented in this chapter. The vim editor is compatible with almost all vi commands and runs on many platforms, including Windows, Macintosh, OS/2, UNIX, and Linux. Refer to the vim home page (www.vim.org) for more information and a very useful Tips section.

What vim is not

The vim editor is not a text formatting program. It does not justify margins or provide the output formatting features of a sophisticated word processing system such as OpenOffice.org Writer. Rather, vim is a sophisticated text editor meant to be used to write code (C, HTML, Java, and so on), short notes, and input to a text formatting system, such as groff or TRoff. You can use fmt (page 664) to do minimal formatting on a text file that you create with vim.

Reading this chapter

Because vim is so large and powerful, this chapter describes only some of its features. Nonetheless, if vim is completely new to you, you may find even this limited set of commands overwhelming. The vim editor provides a variety of ways to accomplish any specified editing task. A useful strategy for learning vim is to begin by learning a subset of commands to accomplish basic editing tasks. Then, as you become more comfortable with the editor, you can learn other commands that enable you to do things more quickly and efficiently. The following tutorial section introduces a basic but useful set of vim commands and features that create and edit a file.
Tutorial: Creating and Editing a File with vim

This section explains how to start vim, enter text, move the cursor, correct text, save the file to the disk, and exit from vim. The tutorial discusses two of the modes of operation of vim and explains how to switch from one mode to the other.

vimtutor

In addition to working with this tutorial, you may want to try vim's tutor, named vimtutor: Give its name as a command to run it.

Specifying a terminal

Because vim takes advantage of features that are specific to various kinds of terminals, you must tell it what type of terminal or terminal emulator you are using. On many systems, and usually when you work on a terminal emulator, your terminal type is set automatically. If you need to specify your terminal type, refer to “Specifying a Terminal” on page 844.

tip: The vi command runs vim

On some systems the command vi runs a minimal build of vim that is compact and faster to load than vim but includes fewer features. See "The compatible Parameter" on page 148 for information on running vim in vi compatible mode.

Starting vim

Start vim with the following command line to create and edit a file named practice:

$ vim practice

When you press RETURN, the command line disappears, and the screen looks similar to the one shown in Figure 6-1.

Figure 6-1. Starting vim
The tildes (~) at the left of the screen indicate that the file is empty. They disappear as you add lines of text to the file. If your screen looks like a distorted version of the one shown, your terminal type is probably not set correctly.

If you start `vim` with a terminal type that is not in the `terminfo` database, `vim` displays an error message and the terminal type defaults to `ansi`, which works on many terminals. In the following example, the user mistyped `vt100` and set the terminal type to `vg100`:

```
Terminal entry not found in terminfo
'vg100' not known. Available builtin terminals are:
  builtin_riscos
  builtin_amiga
  builtin_beos-ansi
  builtin_ansi
  builtin_pcansi
  builtin_win32
  builtin_vt320
  builtin_vt52
```
If you want to reset the terminal type, press ESCAPE and then give the following command to exit from \texttt{vim} and get the shell prompt back:

\texttt{:q!}

When you enter the colon (:), \texttt{vim} moves the cursor to the bottom line of the screen. The characters \texttt{q!} tell \texttt{vim} to quit without saving your work. (You will not ordinarily exit from \texttt{vim} this way because you typically want to save your work.) You must press RETURN after you give this command. Once you get the shell prompt back, refer to "Specifying a Terminal" on page 844, and then start \texttt{vim} again.

If you start it without a filename, \texttt{vim} assumes that you are a novice and tells you how to get started (Figure 6-2).

\textbf{Figure 6-2. Starting \texttt{vim} without a filename}
The practice file is new so it does not contain any text. The vim editor displays a message similar to the one shown in Figure 6-1 on the status (bottom) line of the terminal to show that you are creating and editing a new file. When you edit an existing file, vim displays the first few lines of the file and gives status information about the file on the status line.

Command and Input Modes

Two of vim's modes of operation are Command mode (also called Normal mode) and Input mode (Figure 6-3). While vim is in Command mode, you can give vim commands. For example, you can delete text or exit from vim. You can also command vim to enter Input mode. In Input mode, vim accepts anything you enter as text and displays it on the screen. Press ESCAPE to return vim to Command mode.
By default the \texttt{vim} editor keeps you informed about which mode it is in. You will see \texttt{INSERT} at the lower-left corner of the screen while \texttt{vim} is in Insert mode.

The following command causes \texttt{vim} to display line numbers next to the text you are editing:

\texttt{:set number \textsc{return}}

\texttt{Last Line mode}

The colon (:) in the preceding command puts \texttt{vim} into another mode, \texttt{Last Line mode}. While in this mode, \texttt{vim} keeps the cursor on the bottom line of the screen. When you finish entering the command by pressing \textsc{return}, \texttt{vim} restores the cursor to its place in the text. Give the command \texttt{:set nonumber \textsc{return}} to turn off line numbers.

\texttt{vim} is case sensitive

When you give \texttt{vim} a command, remember that the editor is case sensitive. Thus \texttt{vim} editor interprets the same letter as two different commands, depending on whether you enter an uppercase or lowercase character. Beware of the CAPS LOCK (SHIFTLOCK) key. If you set this key to enter uppercase text while you are in Input mode and then exit to Command mode, \texttt{vim} interprets your commands as uppercase letters. It can be confusing when this happens because \texttt{vim} does not appear to be executing the commands you are entering.

\texttt{Entering Text}

\texttt{Input mode (i/a)}

When you start \texttt{vim}, you must put it in Input mode before you can enter text. To put \texttt{vim} in Input mode, press the \texttt{i} key (insert before the cursor) or the \texttt{a} key (append after the cursor).
If you are not sure whether `vim` is currently in Input mode, press the ESCAPE key; `vim` returns to Command mode if it was in Input mode or beeps, flashes, or does nothing if it is already in Command mode. You can put `vim` back in Input mode by pressing the `i` or `a` key again.

While `vim` is in Input mode, you can enter text by typing on the keyboard. If the text does not appear on the screen as you type, you are not in Input mode.

To continue with this tutorial, enter the sample paragraph shown in Figure 6-4, pressing the RETURN key to end each line. If you do not press RETURN before the cursor reaches the right side of the screen or window, `vim` will wrap the text so that it appears to start a new line. Physical lines will not correspond to programmatic (logical) lines in this situation, and editing will be more difficult.

Figure 6-4. Entering text with `vim`

While you are using `vim`, you can always correct any typing mistakes you make. If you notice a mistake on the line you are entering, you can correct it before you continue (page 146). You can correct other mistakes later. When you finish entering the paragraph, press ESCAPE to return `vim` to Command mode.

**Getting Help**

To get help while you are using `vim`, give the command `:help [feature]` followed by RETURN (you must be in Command mode when you give this command). The colon puts the cursor on the last line of the screen. If you type `:help, vim` displays an introduction to `vim` Help (Figure 6-5). Each dark band near the bottom of the screen names the file that is displayed above it. (Each area of the screen that displays a file, such as the two areas shown in Figure
6-5, is a \texttt{vim} "window.") The \texttt{help.txt} file occupies most of the screen (the upper window) in Figure 6-5. The file that is being edited (\texttt{practice}) occupies a few lines in the lower portion of the screen (the lower window).

Figure 6-5. The main \texttt{vim} Help screen

Read through the introduction to Help by scrolling the text as you read. Pressing \texttt{j} or the DOWN ARROW key moves the cursor down one line at a time; pressing CONTROL-D or CONTROL-U scrolls the cursor down or up half a window at a time. Give the command \texttt{:q!} to close the Help window.

You can get help with the insert commands by giving the command \texttt{:help insert} while \texttt{vim} is in Command mode (Figure 6-6).

Figure 6-6. Help with insert
Correcting Text as You Insert It

The keys that back up and correct a shell command line serve the same functions when vim is in Input mode. These keys include the erase, line kill, and word kill keys (usually CONTROL-H, CONTROL-U, and CONTROL-W, respectively). Although vim may not remove deleted text from the screen as you back up over it, the editor does remove it when you type over it or press RETURN.

Moving the Cursor

You need to be able to move the cursor on the screen so that you can delete, insert, and correct text. While vim is in Command mode, you can use the RETURN key, the SPACE bar, and the ARROW keys to move the cursor. If you prefer to keep your hand closer to the center of the keyboard, if your terminal does not have ARROW keys, or if the emulator you are using does not support them, you can use the h, j, k, and l (lowercase "l") keys to move the cursor left, down, up, and right, respectively.

Deleting Text

Delete character (x) Delete word (dw) Delete line (dd)

You can delete a single character by moving the cursor until it is over the character you want to delete and then giving the command x. You can delete a word by positioning the cursor on the first letter of the word and then giving the command dw (Delete word). You can delete a line of text by moving the cursor until it is anywhere on the
line and then giving the command `dd`.

**Undoing Mistakes**

**Undo (u)**

If you delete a character, line, or word by mistake or give any command you want to undo, give the command `u` (Undo) immediately after the command you want to undo. The `vim` editor will restore the text to the way it was before you gave the last command. If you give the `u` command again, `vim` will undo the command you gave before the one it just undid. You can use this technique to back up over many of your actions. With the `compatible` parameter (page 148) set, `vim` can undo only the most recent change.

**Redo (:redo)**

If you undo a command you did not mean to undo, give a Redo command: CONTROL-R or `:redo` (followed by a RETURN). The `vim` editor will redo the undone command. As with the Undo command, you can give the Redo command many times in a row.

**Entering Additional Text**

**Insert (i) Append (a)**

When you want to insert new text within existing text, move the cursor so it is on the character that follows the new text you plan to enter. Then give the `i` (Insert) command to put `vim` in Input mode, enter the new text, and press ESCAPE to return `vim` to Command mode. Alternatively, you can position the cursor on the character that precedes the new text, and use the `a` (Append) command.

**Open (o and O)**

To enter one or more lines, position the cursor on the line above where you want the new text to go. Give the command `o` (Open). The `vim` editor opens a blank line, puts the cursor on it, and goes into Input mode. Enter the new text, ending each line with a RETURN. When you are finished entering text, press ESCAPE to return `vim` to Command mode. The `O` command works in the same way `o` works, except that it opens a line above the line the cursor is on.

**Correcting Text**

To correct text, use `dd`, `dw`, or `x` to remove the incorrect text. Then use `i`, `a`, `o`, or `O` to insert the correct text.

For example, to change the word `pressing` to `hitting` in Figure 6-4 on page 145 you might use the ARROW keys to move the cursor until it is on top of the `p` in `pressing`. Then give the command `dw` to delete the word `pressing`. Put `vim` in Input mode by giving an `i` command, enter the word `hitting` followed by a SPACE, and press ESCAPE. The word is changed and `vim` is in Command mode, waiting for another command. A shorthand for the two commands `dw` followed by the `i` command is `cw` (Change word). The command `cw` puts `vim` into Input mode.
ti:p: Page breaks for the printer

CONTROL-L is a signal to a printer to skip to the top of the next page. You can enter this character anywhere in a document by pressing CONTROL-L while you are in Input mode. If ^L does not appear, press CONTROL-V before CONTROL-L.

Ending the Editing Session

While you are editing, vim keeps the edited text in an area named the Work buffer. When you finish editing, you must write out the contents of the Work buffer to a disk file so that the edited text is saved and available when you next want it.

Make sure that vim is in Command mode, and then use the ZZ command (you must use uppercase Z’s) to write your newly entered text to the disk and end the editing session. After you give the ZZ command, vim returns control to the shell. You can exit with :q! if you do not want to save your work. Refer to page 188 for a summary of vim commands.

caution: Do not confuse ZZ with CONTROL-Z

When you exit from vim with ZZ, make sure that you type ZZ and not CONTROL-Z (typically the suspend key). When you press CONTROL-Z, vim disappears from your screen, almost as though you had exited from it. In fact, vim will continue running in the background with your work unsaved. Refer to "Job Control" on page 271. If you try to start editing the same file with a new vim command, vim displays a message about a swap file; refer to "File Locks" on page 152.
The compatible Parameter

The `compatible` parameter makes `vim` more compatible with `vi`. By default this parameter is set so that `vim` works like `vi`. If you set up a ~/.vimrc startup file (page 176), the `compatible` parameter is unset and `vim` works like `vim`. To get started with `vim` you can ignore this parameter.

Setting the `compatible` parameter changes many aspects of how `vim` works. For example, when the `compatible` parameter is set, the Undo command (page 146) can undo only your most recent change; with the `compatible` parameter unset, you can call undo repeatedly to undo many changes. This chapter notes when the `compatible` parameter affects a command. To obtain more details on the `compatible` parameter, give the command `:help compatible` RETURN. For a complete list of how `vim` differs from the original `vi`, use `:help vi-diff` RETURN. See page 144 for a discussion of the `help` command.

From the command line use the `C` option to set the `compatible` parameter and the `N` option to unset it. Refer to "Setting Parameters from Within vim“ on page 175 for information on how to change the `compatible` parameter while you are running `vim`. 
Introduction to vim Features

This section covers modes of operation, online help, the Work buffer, emergency procedures, and other vim features. To see which features are incorporated in a particular build, give a vim command followed by the `version` option.

Online Help

As covered briefly earlier, vim provides help while you are using it. Give the command `:help feature` to display information about feature. As you scroll through the various help texts you will see words with a bar on either side, such as `[tutor]`. These words are active links: Move the cursor on top of an active link and press CONTROL-[ to jump to the linked text. Use CONTROL-O (lowercase “o”) to jump back to where you were in the help text. You can also use the active link words in place of feature. For example, you might see the reference `[credits]`; you could enter `:help credits` RETURN to read more about credits. Enter `:q!` to close a help window.

Some common features that you may want to look up using the help system are insert, delete, and opening-window. Although opening-window is not intuitive, you will get to know the names of features as you spend more time with vim. You can also give the command `:help doc-file-list` to view a complete list of the help files. Although vim is a free program, the author requests that you donate the money you would have spent on similar software to help the kids in Uganda (`:help uganda` for more information).

Modes of Operation

The vim editor is part of the ex editor, which has five modes of operation:

- ex Command mode
- ex Input mode
- vim Command mode
- vim Input mode
- vim Last Line mode

While in Command mode, vim accepts keystrokes as commands, responding to each command as you enter it. It does not display the characters you type in this mode. While in Input mode, vim accepts and displays keystrokes as text that it eventually puts into the file you are editing. All commands that start with a colon (:) put vim in Last Line mode. The colon moves the cursor to the bottom line of the screen, where you enter the rest of the command.

In addition to the position of the cursor, there is another important difference between Last Line mode and Command mode. When you give a command in Command mode, you do not terminate the command with a RETURN. However, you must terminate all Last Line mode commands with a RETURN.

You do not normally use the ex modes. When this chapter refers to Input and Command modes, it means the vim modes, not the ex modes.

At the start of an editing session, vim is in Command mode. Several commands, including Insert and Append, put vim in Input mode. When you press the ESCAPE key, vim always reverts to Command mode.

The Change and Replace commands combine the Command and Input modes. The Change command deletes the
text you want to change and puts `vim` in Input mode so you can insert new text. The Replace command deletes the character(s) you overwrite and inserts the new one(s) you enter. Figure 6-3 on page 143 shows the modes and the methods for changing between them.

**tip: Watch the mode and the CAPS LOCK key**

Almost anything you type in Command mode means something to `vim`. If you think that `vim` is in Input mode when it is actually in Command mode, typing in text can produce confusing results. When learning `vim`, make sure that the `showmode` parameter (page 180) is set (it is by default) to remind you which mode you are using. You may also find it useful to turn on the status line by giving a `:set laststatus=2` command (page 178).

Also keep your eye on the CAPS LOCK key. In Command mode typing uppercase letters produces different results than typing lowercase ones. It can be disorienting to give commands and have `vim` give the "wrong" responses.

**The Display**

The `vim` editor uses the status line and several special symbols to give information about what is happening during an editing session.

**Status Line**

The `vim` editor displays status information on the bottom line of the display area. This information includes error messages, information about the deletion or addition of blocks of text, and file status information. In addition, `vim` displays Last Line mode commands on the status line.

**Redrawing the Screen**

Sometimes the screen becomes garbled or overwritten. When `vim` puts characters on the screen, it sometimes leaves @ on a line instead of deleting the line. When output from a program becomes intermixed with the display of the Work buffer things can get confusing. The output does not become part of the Work buffer but affects only the display. If the screen gets overwritten, press ESCAPE to make sure `vim` is in Command mode, and press CONTROL-L to redraw (refresh) the screen.

**Tilde (~) Symbol**

If the end of the file is displayed on the screen, `vim` marks lines that would appear past the end of the file with a tilde (~) at the left of the screen. When you start editing a new file, the `vim` editor marks each line on the screen (except for the first line) with this symbol.

**Correcting Text as You Insert It**

While `vim` is in Input mode, you can use the erase and line kill keys to back up over text so you can correct it. You can also use CONTROL-W to back up over words.

**Work Buffer**
The `vim` editor does all of its work in the Work buffer. At the start of an editing session, `vim` reads the file you are editing from the disk into the Work buffer. During the editing session, it makes all changes to this copy of the file but does not change the file on the disk until you write the contents of the Work buffer back to the disk. Normally when you end an editing session, you command `vim` to write out the contents of the Work buffer, which makes the changes to the text final. When you edit a new file, `vim` creates the file when it writes the contents of the Work buffer to the disk, usually at the end of the editing session.

Storing the text you are editing in the Work buffer has both advantages and disadvantages. If you accidentally end an editing session without writing out the contents of the Work buffer, your work is lost. However, if you unintentionally make some major changes (such as deleting the entire contents of the Work buffer), you can end the editing session without implementing the changes.

If you want to use `vim` to look at a file but not to change it, you can use the `view` utility:

```
$ view filename
```

Calling the `view` utility is the same as calling the `vim` editor with the `-R` (readonly) option. Once you have invoked the editor in this way, you cannot write the contents of the Work buffer back to the file whose name appeared on the command line. You can always write the Work buffer out to a file with a different name.

**Line Length and File Size**

The `vim` editor operates on any format file, provided the length of a single "line" (that is, the characters between two NEWLINE characters) can fit into available memory. The total length of the file is limited only by available disk space and memory.

**Windows**

The `vim` editor allows you to open, close, and hide multiple windows, each of which allows you to edit a different file. Most of the window commands consist of CONTROL-W followed by another letter. For example, CONTROL-W s opens another window (splits the screen) that is editing the same file. CONTROL-W n opens a second window that is editing an empty file. CONTROL-W w moves the cursor between windows, and CONTROL-W q (or :q) quits (closes) a window. Give the command `:help windows` to display a complete list of windows commands.

**File Locks**

When you edit an existing file, `vim` displays the first few lines of the file, gives status information about the file on the status line, and locks the file. When you try to open a locked file with `vim`, you will see a message similar to the one shown in Figure 6-7. You will see this type of message in two cases: when you try to edit a file that someone is already editing (perhaps you are editing it in another window or on another terminal) or when you try to edit a file that you were editing when `vim` or the system crashed.

*Figure 6-7. Attempting to open a locked file*
Although it is advisable to follow the instructions that `vim` displays, a second user can edit a file and write it out with a different filename. Refer to the next sections for more information.

**Abnormal Termination of an Editing Session**

You can end an editing session in one of two ways: When you exit from `vim`, you can save the changes you made during the editing session or you can abandon those changes. You can use the `ZZ` or `:wq` command from Command mode to save your changes and exit from `vim` (see "Ending the Editing Session" on page 147).

To end an editing session without writing out the contents of the Work buffer, give the following command:

```
:q!
```

When you use this command to end an editing session, `vim` does not preserve the contents of the Work buffer, so you will lose all the work you did since the last time you wrote the Work buffer to disk. The next time you edit or use the file, it will appear as it did the last time you wrote the Work buffer to disk. Use the `:q!` command cautiously.

Sometimes you may find that you created or edited a file but `vim` will not let you exit. For example, if you forgot to specify a filename when you first called `vim`, you will get a message saying No file name when you give a `ZZ` command. If `vim` does not let you exit normally, you can use the Write command (`:w`) to name the file and write it to disk before you quit `vim`. Give the following command, substituting the name of the file for `filename` (remember to follow the command with a RETURN):

```
:w
filename
```
After you give the Write command, you can use `:q` to quit using `vim`. You do not need to use the exclamation point (as in `q!`); it is necessary only when you have made changes since the last time you wrote the Work buffer to disk. Refer to page 174 for more information about the Write command.

**tip: When you cannot write to a file**

It may be necessary to write a file using `:w filename` if you do not have write permission for the file you are editing. If you give a `ZZ` command and see the message "`filename` is read only", you do not have write permission for the file. Use the Write command with a temporary filename to write the file to disk under a different filename. If you do not have write permission for the working directory, `vim` may still not be able to write the file to the disk. Give the command again, using an absolute pathname of a dummy (nonexistent) file in your home directory in place of the filename. (For example, Alex might give the command `:w /home/alex/temp` or `:w ~/temp`.)

If `vim` reports File exists, you will need to use `:w! filename` to overwrite the existing file (make sure that you want to do this). Refer to page 175.

**Recovering Text After a Crash**

The `vim` editor temporarily stores the file you are working on in a swap file. If the system crashes while you are editing a file with `vim`, you can often recover its text from the swap file. When you attempt to edit a file that has a swap file, you will see a message similar to the one shown in Figure 6-7 on page 152. If someone else is editing the file, quit or open the file as a readonly file.

Alex checks whether the swap file exists for a file named memo, which he was editing when the system went down:

```
$ vim -r
Swap files found:

In current directory:
1. .memo.swp
   dated: Mon Oct 18 13:16:06 2004
   owned by: alex
   file name: ~alex/memo
   host name: bravo.example.com
   user name: alex
   process ID: 19786

In directory ~/tmp:
   -- none --
```
With the `r` option `vim` displays a list of any swap files that it has saved (some may be old). If your work was saved, give the same command followed by a SPACE and the name of the file. You will then be editing a recent copy of your Work buffer. Use `:w filename` immediately to save the salvaged copy of the Work buffer to disk under a name different from the original file. Then check the recovered file to make sure it is OK. Following is Alex's exchange with `vim` as he recovers `memo`. Subsequently he deletes the swap file:

```
$ vim -r memo
Using swap file "./memo.swp"
Original file "~/memo"
Recovery completed. You should check if everything is OK.
(You might want to write out this file under another name
and run diff with the original file to check for changes)
Delete the .swp file afterwards.

Hit ENTER or type command to continue
:w memo2
    :q
$ rm .memo.swp
```

**tip: You must recover files on the system you were using**

The recovery feature of `vim` is specific to the system you were using when the crash occurred. If you are running on a cluster, you must log in on the system you were using before the crash to use the `r` option.
Command Mode: Moving the Cursor

While vim is in Command mode, you can position the cursor over any character on the screen. You can also display a different portion of the Work buffer on the screen. By manipulating the screen and cursor position, you can place the cursor on any character in the Work buffer.

You can move the cursor forward or backward through the text. As illustrated in Figure 6-8, forward means toward the right and bottom of the screen and the end of the file. Backward means toward the left and top of the screen and the beginning of the file. When you use a command that moves the cursor forward past the end (right) of a line, the cursor generally moves to the beginning (left) of the next line. When you move it backward past the beginning of a line, the cursor moves to the end of the previous line.

Figure 6-8. Forward and backward

Long lines

Sometimes a line in the Work buffer may be too long to appear as a single line on the screen. In such a case vim wraps the current line onto the next line (unless you set the nowrap option [page 178]).

You can move the cursor through the text by any Unit of Measure (that is, character, word, line, sentence, paragraph, or screen). If you precede a cursor-movement command with a number, called a Repeat Factor, the cursor moves that number of units through the text. Refer to pages 184 and 187 for more precise definitions of these terms.

Moving the Cursor by Characters

l/h

The SPACE bar moves the cursor forward, one character at a time, toward the right side of the screen. The l (lowercase "l") key and the RIGHT ARROW key (Figure 6-9) do the same thing. The command 7 SPACE or 7l moves the cursor seven characters to the right. These keys cannot move the cursor past the end of the current line to the beginning of the next line. The h and LEFT ARROW keys are similar to the l key but work in the opposite direction.

Figure 6-9. Moving the cursor by characters
Moving the Cursor to a Specific Character

f/F

You can move the cursor to the next occurrence of a specified character on the current line by using the Find command. For example, the following command moves the cursor from its current position to the next occurrence of the character a, if one appears on the same line:

fa

You can also find the previous occurrence by using a capital F. The following command moves the cursor to the position of the closest previous a in the current line:

Fa

A semicolon (;) repeats the last Find command.

Moving the Cursor by Words

w/W

The w (word) key moves the cursor forward to the first letter of the next word (Figure 6-10). Groups of punctuation count as words. This command goes to the next line if the next word is located there. The command 15w moves the cursor to the first character of the fifteenth subsequent word.

Figure 6-10. Moving the cursor by words

The W key is similar to the w key but moves the cursor by blank-delimited words, including punctuation, as it skips forward. (Refer to "Blank-Delimited Word" on page 185.)
The b (back) key moves the cursor backward to the first letter of the previous word. The B key moves the cursor backward by blank-delimited words. Similarly the e key moves the cursor to the end of the next word; E moves it to the end of the next blank-delimited word.

**Moving the Cursor by Lines**

j/k

The RETURN key moves the cursor to the beginning of the next line; the j and DOWN ARROW keys move it down one line to the character just below the current character (Figure 6-11). If no character is immediately below the current character, the cursor moves to the end of the next line. The cursor will not move past the last line of text in the work buffer.

![Figure 6-11. Moving the cursor by lines](image)

The k and UP ARROW keys are similar to the j key but work in the opposite direction. The minus (−) key is similar to the RETURN key but works in the opposite direction.

**Moving the Cursor by Sentences and Paragraphs**

)}{(}

The ) and } keys move the cursor forward to the beginning of the next sentence or the next paragraph, respectively (Figure 6-12). The ( and { keys move the cursor backward to the beginning of the current sentence or paragraph. You can find more information on sentences and paragraphs starting on page 186.

![Figure 6-12. Moving the cursor by sentences, paragraphs, H, M, and L](image)
Moving the Cursor Within the Screen

H/M/L

The H (home) key positions the cursor at the left end of the top line of the screen. The M (middle) key moves the cursor to the middle line, and the L (lower) key moves it to the bottom line (Figure 6-12).

Viewing Different Parts of the Work Buffer

The screen displays a portion of the text that is in the Work buffer. You can display the text preceding or following the text on the screen by scrolling the display. You can also display a portion of the Work buffer based on a line number.

CONTROL-D CONTROL-U

Press CONTROL-D to scroll the screen down (forward) through the file so that vim displays half a screen of new text. Use CONTROL-U to scroll the screen up (backward) by the same amount. If you precede either of these commands with a number, vim will scroll that number of lines each time you use CONTROL-D or CONTROL-U for the rest of the session (unless you again change the number of lines to scroll). See page 179 for a discussion of the scroll parameter.

CONTROL-F CONTROL-B

The CONTROL-F (forward) and CONTROL-B (backward) keys display almost a whole screen of new text, leaving a couple of lines from the previous screen for continuity. On many keyboards you can use the PAGE DOWN and PAGE UP keys in place of CONTROL-F and CONTROL-B.

Line numbers (G)
When you enter a line number followed by G (goto), `vim` positions the cursor on that line in the Work buffer. If you press G without a number, `vim` positions the cursor on the last line in the Work buffer. Line numbers are implicit; your file does not need to have actual line numbers for this command to work. Refer to "Line numbers" on page 178 if you want `vim` to display line numbers.
**Input Mode**

The Insert, Append, Open, Change, and Replace commands put *vim* in Input mode. While *vim* is in this mode, you can put new text into the Work buffer. You need to press the ESCAPE key to return *vim* to Command mode when you finish entering text. Refer to "Show mode" on page 180 if you want *vim* to remind you when it is in Input mode (it does by default).

**Inserting Text**

**Insert (i/I)**

The `i` (Insert) command puts *vim* in Input mode and places the text you enter before the character the cursor is on (the *current character*). The `I` command places text at the beginning of the current line (Figure 6-13). Although the `i` and `I` commands sometimes overwrite text on the screen, the characters in the Work buffer are not changed; only the display is affected. The overwritten text is redisplayed when you press ESCAPE and *vim* returns to Command mode. Use `i` or `I` to insert a few characters or words into existing text or to insert text in a new file.

*Figure 6-13. The I, i, a, and A commands*

![Image](image_url)

**Appending Text**

**Append (a/A)**

The `a` (Append) command is similar to the `i` command, except that it places the text you enter after the current character (Figure 6-13). The `A` command places the text after the last character on the current line.

**Opening a Line for Text**

**Open (o/O)**

The `o` (Open) and `O` commands open a blank line within existing text, place the cursor at the beginning of the new (blank) line, and put *vim* in Input mode. The `O` command opens a line above the current line; `o` opens one below the current line. Use the Open commands when you are entering several new lines within existing text.

**Replacing Text**

**Replace (r/R)**

The `r` and `R` (Replace) commands cause the new text you enter to overwrite (replace) existing text. The single
character you enter following an r command overwrites the current character. After you enter that character, vim automatically returns to Command mode; you do not need to press the ESCAPE key.

The R command causes all subsequent characters to overwrite existing text until you press ESCAPE to return vim to Command mode.

**tip: Replacing TABs**

The Replace commands may appear to behave strangely when you replace TAB characters. TAB characters can appear as several SPACES until you try to replace them. They are actually only one character and are replaced by a single character. Refer to "Invisible characters" on page 178 for information on how to display TABs as visible characters.

**Quoting Special Characters in Input Mode**

**CONTROL-V**

While you are in Input mode, you can use the Quote command, CONTROL-V, to enter any character into the text, including characters that normally have special meaning to vim. Among these characters are CONTROL-L (or CONTROL-R), which redraws the screen; CONTROL-W, which backs the cursor up a word to the left; and ESCAPE, which ends Input mode.

To insert one of these characters into the text, type CONTROL-V followed by the character. CONTROL-V quotes the single character that follows it. For example, to insert the sequence ESCAPE[2J into a file you are creating in vim, you type the character sequence CONTROL-V ESCAPE[2J. This character sequence clears the screen of a DEC VT-100 and other similar terminals. Although you would not ordinarily want to type this sequence into a document, you might want to use it or another ESCAPE sequence in a shell script you are creating in vim. Refer to Chapter 11 for information about writing shell scripts.
Command Mode: Deleting and Changing Text

This section describes the commands to delete and replace, or change, text in the document you are editing. The Undo command is covered here because it allows you to restore deleted or changed text.

Undoing Changes

Undo (u/U)

The u command (Undo) restores text that you just deleted or changed by mistake. A single Undo command restores only the most recently deleted text. If you delete a line and then change a word, the first Undo restores only the changed word; you have to give a second Undo command to restore the deleted line. The U command restores the last line you changed to the way it was before you started changing it, even after several changes.

Deleting Characters

Delete character (x/X)

The x command deletes the current character. You can precede the x command by a Repeat Factor (page 187) to delete several characters on the current line, starting with the current character. The X command deletes characters to the left of the cursor.

Deleting Text

Delete (d/D)

The d (Delete) command removes text from the Work buffer. The amount of text that d removes depends on the Repeat Factor and the Unit of Measure (page 184) you enter after the d. After the text is deleted, vim is still in Command mode.

**tip: Use dd to delete a single line**

The command d RETURN deletes two lines: the current line and the following one. Use dd to delete just the current line, or precede dd by a Repeat Factor (page 187) to delete several lines.

You can delete from the current cursor position up to a specific character on the same line. To delete up to the next semicolon (;), give the command dt; (see page 164 for more information on the t command). To delete the remainder of the current line, use D or d$. Table 6-1 lists some Delete commands. Each command, except the last group that starts with dd, deletes from/to the current character.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>

<td>Deletes from first line on screen</td>
</tr>
<tr>
<td>dG</td>
<td>Deletes through end of Work buffer</td>
</tr>
<tr>
<td>d1G</td>
<td>Deletes from beginning of Work buffer</td>
</tr>
</tbody>
</table>

**tip: Exchange characters and lines**

If two characters are out of order, position the cursor on the first character and give the commands `xp`.

If two lines are out of order, position the cursor on the first line and give the commands `ddp`.

See page 172 for more information on the Put commands.

## Changing Text

**Change (c/C)**

The `c` (Change) command replaces existing text with new text. The new text does not have to occupy the same space as the existing text. You can change a word to several words, a line to several lines, or a paragraph to a single character. The `C` command replaces the text from the cursor position to the end of the line.

The `c` command deletes the amount of text specified by the Repeat Factor and the **Unit of Measure** (page 184) and puts `vim` in Input mode. When you finish entering the new text and press ESCAPE, the old word, line, sentence, or paragraph is changed to the new one. Pressing ESCAPE without entering new text deletes the specified text (replaces the specified text with nothing).

Table 6-2 lists some Change commands. Except for the last two, each command changes text from/to the current character.
Table 6-2. Change command examples

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>cl</td>
<td>Changes current character</td>
</tr>
<tr>

<td>Changes to end of line</td>
</tr>
<tr>
<td>cc</td>
<td>Changes the current line</td>
</tr>
<tr>
<td>5cc</td>
<td>Changes five lines starting with the current line</td>
</tr>
</tbody>
</table>

**tip: dw works differently from cw**

The *dw* command deletes all the characters through (including) the SPACE at the end of a word. The *cw* command changes only the characters in the word, leaving the trailing SPACE intact.

Replacing Text

Substitute (s/S)

The *s* and *S* (Substitute) commands also replace existing text with new text (Table 6-3). The *s* command deletes the character the cursor is on and puts vim into Input mode. It has the effect of replacing the single character that the cursor is on with whatever you type until you press ESCAPE. The *S* command does the same thing as the *cc* command: It changes the current line. The *s* command replaces characters only on the current line. If you specify a Repeat Factor before an *s* command and this action would replace more characters than exist on the current line, *s* changes characters only to the end of the line (same as *C*).

Table 6-3. Substitute command examples

<table>
<thead>
<tr>
<th>Command</th>

<td>5s</td>
<td>Substitutes one or more characters for five characters, starting with current character</td>
</tr>
</tbody>
</table>
Changing Case

The tilde (~) character changes the case of the character under the cursor from uppercase to lowercase, or vice versa. You can precede the tilde with a number to specify the number of characters you want the command to affect. For example, 5~ will transpose the next five characters starting with the character under the cursor, but it will not transpose characters past the end of the line the cursor is on.
Searching and Substituting

Searching for and replacing a character, a string of text, or a string that is matched by a regular expression is a key feature of any editor. The `vim` editor provides simple commands for searching for a character on the current line. It also provides more complex commands for searching for and optionally substituting for single and multiple occurrences of strings or regular expressions anywhere in the Work buffer.

Searching for a Character

Find (f/F)

You can search for and move the cursor to the next occurrence of a specified character on the current line using the `f` (Find) command. Refer to "Moving the Cursor to a Specific Character" on page 155.

`t/T`

The next two commands are used in the same manner as the Find command. The `t` command places the cursor on the character before the next occurrence of the specified character. The `T` command places the cursor on the character after the previous occurrence of the specified character.

A semicolon (;) repeats the last `f, F, t`, or `T` command.

You can combine these search commands with other commands. For example, the command `d2fq` deletes the text from the location of the cursor to the second occurrence of the letter `q` on the current line.

Searching for a String

The `vim` editor can search backward or forward through the Work buffer to find a string of text or a string that matches a regular expression (see Appendix A). To find the next occurrence of a string (forward), press the forward slash (/) key, enter the text you want to find (called the search string), and press RETURN. When you press the slash key, `vim` displays a slash on the status line. As you enter the string of text, it is also displayed on the status line. When you press RETURN, `vim` searches for the string. If this search is successful, `vim` positions the cursor on the first character of the string. If you use a question mark (?) in place of the forward slash, `vim` searches for the previous occurrence of the string. If you need to include a forward slash in a forward search or a question mark in a backward search, you must quote it by preceding it with a backslash (\).

**tip: Two distinct ways of quoting characters**

You use CONTROL-V to quote special characters in text that you are entering into a file (page 159). This section discusses the use of a backslash (\) to quote special characters in a search string. The two techniques of quoting characters are not interchangeable.

The `N` and `n` keys repeat the last search without any need for you to reenter the search string. The `n` key repeats the original search exactly, and the `N` key repeats the search in the opposite direction of the original search.

If you are searching forward and `vim` does not find the search string before it gets to the end of the Work buffer, the editor typically wraps around and continues the search at the beginning of the Work buffer. During a backward search, `vim` wraps around from the beginning of the Work buffer to the end. Also, `vim` normally performs case-sensitive searches. Refer to "Wrap scan" (page 180) and "Ignore case in searches" (page 178) for information about how to change these search parameters.
Normal Versus Incremental Searches

When `vim` performs a normal search (its default behavior), you enter a slash or question mark followed by the search string and press RETURN. The `vim` editor moves the cursor to the next or previous occurrence of the string you are searching for.

When `vim` performs an incremental search, you enter a slash or question mark. As you enter each character of the search string, `vim` moves the highlight to the next or previous occurrence of the string you have entered so far. When the highlight is on the string you are searching for, you must press RETURN to move the cursor to the highlighted string. If the string you enter does not match any text, `vim` does not highlight anything.

The type of search that `vim` performs depends on the `incsearch` parameter (page 178). Give the command `:set incsearch` to turn on incremental searching. Use `noincsearch` to turn it off. When you set the `compatible` parameter (page 148), `vim` turns off incremental searching.

Special Characters in Search Strings

Because the search string is a regular expression, some characters take on a special meaning within the search string. The following paragraphs list some of these characters. See also "Extended Regular Expressions" on page 834.

The first two items in the following list (^ and $) always have their special meanings within a search string unless you quote them by preceding them with a backslash (\). You can turn off the special meanings within a search string for the rest of the items in the list by setting the `nomagic` parameter. See "Allow special characters in searches" (page 177) for more information.

^ Beginning-of-Line Indicator

When the first character in a search string is a caret (also called a circumflex) it matches the beginning of a line. For example, the command `/^the` finds the next line that begins with the string the.

$ End-of-Line Indicator

A dollar sign matches the end of a line. For example, the command `/!$` finds the next line that ends with an exclamation point and `/ $` matches the next line that ends with a SPACE.

. Any-Character Indicator

A period matches any character, anywhere in the search string. For example, the command `/.e` finds line, followed, like, included, all memory, or any other word or character string that contains an l followed by any two characters and an e. To search for a period, use a backslash to quote the period (\.).

\ > End-of-Word Indicator

This pair of characters matches the end of a word. For example, the command `/s\>` finds the next word that ends with an s. Whereas a backslash (\) is typically used to turn off the special meaning of a character, the character sequence `\>` has a special meaning, while > alone does not.
\ < Beginning-of-Word Indicator

This pair of characters matches the beginning of a word. For example, the command `/<The` finds the next word that begins with the string The. The beginning-of-word indicator uses the backslash in the same, atypical way as the end-of-word indicator.

* Zero or More Occurrences

This character is a modifier that will match zero or more occurrences of the character immediately preceding it. For example, the command `/dis-m` will match the string di followed by zero or more s characters followed by an m. Examples of successful matches are dim or dism or diss.

[ ] Character-Class Definition

Brackets surrounding two or more characters match any single character located between the brackets. For example, the command `/dis[ck]` finds the next occurrence of either disk or disc.

There are two special characters you can use within a character-class definition. A caret (^) as the first character following the left bracket defines the character class to be any except the following characters. A hyphen between two characters indicates a range of characters. Refer to the examples in Table 6-4.

<table>
<thead>
<tr>
<th>Search string</th>
<th>What it finds</th>
</tr>
</thead>
<tbody>
<tr>
<td>/and</td>
<td>Finds the next occurrence of the string and</td>
</tr>
<tr>
<td>\ &lt;and\ &gt;</td>
<td>Finds the next occurrence of the word and</td>
</tr>
<tr>
<td>/ ^The</td>
<td>Finds the next line that starts with The</td>
</tr>
<tr>
<td>/ ^[0-9][0-9])</td>
<td>Finds the next line that starts with a two-digit number followed by a right parenthesis</td>
</tr>
<tr>
<td>\ &lt;[adr]</td>
<td>Finds the next word that starts with an a, d, or r</td>
</tr>
</tbody>
</table>

Examples: sand and standard slander andiron

Table 6-4. Search examples
Search string                     What it finds

Examples: apple drive road argument right
/^/[A-Za-z]  Finds the next line that starts with an uppercase or lowercase letter

Examples:

will not find a line starting with the number 7 . . .
Dear Mr. Jones . . .
in the middle of a sentence like this . . .

Substituting One String for Another

A Substitute command combines the effects of a Search command and a Change command. That is, it searches for a string (regular expression) just as the / command does, allowing the same special characters discussed in the previous section. When it finds the string or matches the regular expression, the Substitute command changes the string or regular expression it matches. The syntax of the Substitute command is

```
:g[/search-string/replacement-string[/option]]
```

As with all commands that begin with a colon, vim executes a Substitute command from the status line.

The Substitute Address

If you do not specify an address, Substitute searches only the current line. If you use a single line number as the address, Substitute searches that line. If the address is two line numbers separated by a comma, Substitute searches those lines and the lines between them. Refer to "Line numbers" on page 178 if you want vim to display line numbers. Wherever a line number is allowed in the address, you may also use an address-string enclosed between slashes. The vim editor operates on the next line that the address-string matches. When you precede the first slash of the address-string with the letter g (for global), vim operates on all lines in the file that the address-string matches. (This g is not the same as the one that goes at the end of the Substitute command to cause multiple replacements on a single line; see "Searching for and Replacing Strings" below).

Within the address, a period represents the current line, a dollar sign represents the last line in the Work buffer, and a percent sign represents the entire Work buffer. You can perform address arithmetic using plus and minus signs. Table 6-5 shows some examples of addresses.

<table>
<thead>
<tr>
<th>Address</th>
<th>Portion of Work buffer addressed</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Line 5</td>
</tr>
<tr>
<td>77,100</td>
<td>Lines 77 through 100 inclusive</td>
</tr>
<tr>
<td>1,</td>
<td>Beginning of Work buffer through current line</td>
</tr>
<tr>
<td>..,$</td>
<td>Current line through end of Work buffer</td>
</tr>
</tbody>
</table>
Address Portion of Work buffer addressed
1,$ Entire Work buffer
% Entire Work buffer
/pine/ The next line containing the word pine
g/pine/ All lines containing the word pine
..+10 Current line through tenth following line (11 lines in all)

Searching for and Replacing Strings

An s comes after the address in the command syntax, indicating that this is a Substitute command. A delimiter follows the s, marking the beginning of the search-string. Although the examples in this book use a forward slash, you can use as a delimiter any character that is not a letter, number, blank, or backslash. You must use the same delimiter at the end of the search-string.

Next comes the search-string. It has the same format as the search string in the / command and can include the same special characters (page 165). (The search-string is a regular expression; refer to Appendix A for more information.) Another delimiter marks the end of the search-string and the beginning of the replace-string.

The replace-string replaces the text matched by the search-string. It should be followed by the delimiter character. You can omit the final delimiter when no option follows the replace-string; a final delimiter is required if an option is present.

Several characters have special meanings in the search-string, and other characters have special meanings in the replace-string. For example, an ampersand (&) in the replace-string represents the text that was matched by the search-string. A backslash in the replace-string quotes the character that follows it. Refer to Table 6-6 and Appendix A.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>:s/bigger/biggest/</td>
<td>Replaces the first occurrence of the string bigger on the current line with biggest</td>
</tr>
</tbody>
</table>

Example:

bigger $\rightarrow$ biggest

:1,.s/Ch 1/Ch 2/g | Replaces every occurrence of the string Ch 1, before or on the current line, with the string Ch 2 |

Examples:

Ch 1 $\rightarrow$ Ch 2

Ch 12 $\rightarrow$ Ch 22

:1,$s/ten/10/g | Replaces every occurrence of the string ten with the string 10 |

Examples:

ten $\rightarrow$ 10
<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>often → of10</td>
<td></td>
</tr>
<tr>
<td>tenant → 10ant</td>
<td></td>
</tr>
</tbody>
</table>

`:g/chapter/s/ten/10/` Replaces the first occurrence of the string `ten` with the string `10` on all lines containing the word `chapter`.

Examples:

- `chapter ten → chapter 10`
- `chapters will often → chapters will of10`

`:%s/\<ten\>/10/g` Replaces every occurrence of the word `ten` with the string `10`.

Example:

- `ten → 10`

`:,.+10s/every/each/g` Replaces every occurrence of the string `every` with the string `each` on the current line through the tenth following line.

Examples:

- `every → each`
- `everything → eachthing`

`:s/\<short\>/"&"/` Replaces the word `short` on the current line with "short" (enclosed within quotation marks).

Example:

- `the shortest of the short → the shortest of the "short"`

Normally, the Substitute command replaces only the first occurrence of any text that matches the `search-string` on a line. If you want a global substitution—that is, if you want to replace all matching occurrences of text on a line—append the `g` (global) option after the delimiter that ends the `replace-string`. Another useful option, `c` (check), causes `vim` to ask whether you would like to make the change each time it finds text that matches the `search-string`. Pressing `y` replaces the `search-string`, `q` terminates the command, `I` (last) makes the replacement and quits, `a` (all) makes all remaining replacements, and `n` continues the search without making that replacement.

The `address-string` need not be the same as the `search-string`. For example,

`:/candle/s/wick/flame/

substitutes `flame` for the first occurrence of `wick` on the next line that contains the string `candle`. Similarly,

`:g/candle/s/wick/flame/

performs the same substitution for the first occurrence of `wick` on each line of the file containing the string `candle` and
:\g/candle/s/wick/flame/g

performs the same substitution for all occurrences of wick on each line that contains the string candle.

If the search-string is the same as the address, you can leave the search-string blank. For example, the command :/:candle/s//lamp/ is equivalent to the command :/:candle/s/candle/lamp/.
Miscellaneous Commands

This section describes three commands that do not fit naturally into any other groups.

Join

Join (J)

The \texttt{J} (Join) command joins the line below the current line to the end of the current line, inserting a SPACE between what was previously two lines and leaving the cursor on this SPACE. If the current line ends with a period, \texttt{vim} inserts two SPACES.

You can always "unjoin" (break) a line into two lines by replacing the SPACE or SPACES where you want to break the line with a RETURN.

Status

Status (\texttt{CONTROL-G})

The Status command, \texttt{CONTROL-G}, displays the name of the file you are editing, information about whether the file has been modified, the total number of lines in the Work buffer, the percentage of the Work buffer preceding the current line, and the number of the line and character the cursor is on. You can also use \texttt{:f} to display status information. Following is a sample status line:

"termcap" 17103 lines --3%-- 569, 1

. (Period)

The . (period) command repeats the most recent command that made a change. If you had just given a \texttt{d2w} command (delete the next two words), for example, the . command would delete the next two words. If you had just inserted text, the . command would repeat the insertion of the same text. This command is useful if you want to change some occurrences of a word or phrase in the Work buffer. Search for the first occurrence of the word (use \texttt{/}) and then make the change you want (use \texttt{cw}). You can then use \texttt{n} to search for the next occurrence of the word and . to make the same change to it. If you do not want to make the change, use \texttt{n} again to find the next occurrence.
Yank, Put, and Delete Commands

The `vim` editor has a General-Purpose buffer and 26 Named buffers that can hold text during an editing session. These buffers are useful if you want to move or copy a portion of text to another location in the Work buffer. A combination of the Delete and Put commands removes text from one location in the Work buffer and places it in another location in the Work buffer. The Yank and Put commands copy text to another location in the Work buffer, without changing the original text.

The General-Purpose Buffer

The `vim` editor stores the text that you most recently changed, deleted, or yanked in the General-Purpose buffer. The Undo command retrieves text from the General-Purpose buffer when it restores text.

Copying Text to the Buffer

Yank (y/Y)

The Yank command (y) is identical to the Delete (d) command except that it does not delete text from the Work buffer. The `vim` editor places a copy of the yanked text in the General-Purpose buffer. You can then use a Put command to place another copy of it elsewhere in the Work buffer. Use the Yank command just as you use the Delete command. The uppercase Y command yanks an entire line into the General-Purpose buffer.

> tip: Use yy to yank one line

Just as d RETURN deletes two lines, so y RETURN yanks two lines. Use the yy command to yank and dd to delete the current line.

> tip: D works differently from Y

The D command (page 160) does not work in the same manner as the Y command. Whereas D deletes to the end of the line, Y yanks the entire line regardless of the cursor position.

Copying Text From the Buffer

Put (p/P)

The Put commands, p and P, copy text from the General-Purpose buffer to the Work buffer. If you delete or yank characters or words into the General-Purpose buffer, p inserts them after the current character, and P inserts them before this character. If you delete or yank lines, sentences, or paragraphs, P inserts the contents of the General-Purpose buffer before the line the cursor is on, and p inserts them after this line.

Put commands do not destroy the contents of the General-Purpose buffer. Thus you can place the same text at several points within the file by using one Delete or Yank command and several Put commands.

Deleting Text Copies It into the Buffer

Any of the Delete commands described earlier in this chapter (page 160) place the deleted text in the General-Purpose buffer. Just as you can use the Undo command to put the deleted text back where it came from, so you can
use a Put command to put the deleted text at another location in the Work buffer.

For example, if you delete a word from the middle of a sentence by using the \texttt{dw} command and then move the cursor to a SPACE between two words and give a \texttt{p} command, \texttt{vim} places the word you just deleted at the new location. If you delete a line using the \texttt{dd} command and then move the cursor to the line \textit{below} the line where you want the deleted line to appear and give a \texttt{P} command, \texttt{vim} places the line at the new location.
optional: Named Buffers

You can use a Named buffer with any of the Delete, Yank, or Put commands. Each of the 26 Named buffers is named by a letter of the alphabet. Each Named buffer can store a different block of text so that you can recall each block as needed. Unlike the General-Purpose buffer, vim does not change the contents of a Named buffer unless you use a command that specifically overwrites that buffer. The vim editor maintains the contents of the Named buffers throughout an editing session.

The vim editor stores text in a Named buffer if you precede a Delete or Yank command with a double quotation mark (" ) and a buffer name (for example, " kyy yanks a copy of the current line into buffer k ). You can use a Named buffer in two ways. First, if you give the name of the buffer as a lowercase letter, vim overwrites the contents of the buffer when it deletes or yanks text into the buffer. Second, if you use an uppercase letter for the buffer name, vim appends the newly deleted or yanked text to the end of the buffer. This feature enables you to collect blocks of text from various sections of a file and deposit them at one place in the file with a single command. Named buffers are also useful when you are moving a section of a file and do not want to use a Put command immediately after the corresponding Delete command, and when you want to insert a paragraph, sentence, or phrase repeatedly in a document.

If you have one sentence that you use throughout a document, you can yank that sentence into a Named buffer and put it wherever you need it by using the following procedure: After entering the first occurrence of the sentence and pressing ESCAPE to return to Command mode, leave the cursor on the line containing the sentence. (The sentence must appear on a line or lines by itself for this procedure to work.) Then yank the sentence into Named buffer a by giving the " ayy command (or " a2yy if the sentence takes up two lines). Now anytime you need the sentence, you can return to Command mode and give the command " ap to put a copy of the sentence below the line the cursor is on.

This technique provides a quick and easy way to insert text that you use frequently in a document. For example, if you were editing a legal document, you might store the phrase The Plaintiff alleges that the Defendant in a Named buffer to save yourself the trouble of typing it every time you want to use it. Similarly, if you were creating a letter that frequently used a long company name, such as National Standards Institute, you might put it into a Named buffer.

NUMBERED BUFFERS

In addition to the 26 Named buffers and 1 General-Purpose buffer, 9 Numbered buffers are available. They are, in one sense, readonly buffers. The vim editor fills them with the nine most recently deleted chunks of text that are at least one line long. The most recently deleted pattern is held in " 1 , the next most recent in " 2 , and so on. If you delete a block of text and then give other vim commands so that you cannot reclaim the deleted text with Undo, use " 1p to paste the most recently deleted chunk of text below the location of the cursor. If you have deleted several blocks of text and want to reclaim a specific one, proceed as follows: Paste the contents of the first buffer with " 1p . If the first buffer does not have the text you are looking for, undo the paste with u and then give the period (.) command to repeat the previous command. The Numbered buffers work in a unique way with the period command: Instead of pasting the contents of buffer " 1 , the period command pastes the contents of the next buffer (" 2 ). Another u and period replace the contents of buffer " 2 with that of buffer " 3 , and so on through the nine buffers.
Reading and Writing Files

Exit (ZZ)

The `vim` editor reads a disk file into the Work buffer when you specify a filename on the command line you use to call `vim`. The `ZZ` command that terminates the editing session writes the contents of the Work buffer back to the disk file. This section discusses other ways of reading text into the Work buffer and writing it to a file.

Reading Files

Read (:r)

The Read command reads a file into the Work buffer. The new file does not overwrite any text in the Work buffer but rather is positioned following the single address you specify (or the current line if you do not specify an address). You can use an address of 0 to read the file into the beginning of the Work buffer. The Read command has the following syntax:

```
:[address] r [filename]
```

As with other commands that begin with a colon, when you enter the colon it appears on the status line. The `filename` is the pathname of the file that you want to read and must be terminated by RETURN. If you omit the `filename`, `vim` reads the file you are editing from the disk.

Writing Files

Write (:w)

The Write command writes part or all of the Work buffer to a file. You can use an address to write out part of the Work buffer and a filename to specify a file to receive the text. If you do not use an address or filename, `vim` writes the entire contents of the Work buffer to the file you are editing, updating the file on the disk.

During a long editing session, it is a good idea to use the Write command occasionally. If a problem later develops, a recent copy of the Work buffer is then safe on the disk. If you use a `:q!` command to exit from `vim`, the disk file reflects the version of the Work buffer at the time you last used the Write command. The Write command has two possible formats:

```
:[address] w[!] [filename]
```

`: [address]`
The second format appends text to an existing file. The address specifies the portion of the Work buffer vim will write to the file. The address follows the form of the address that the Substitute command uses (page 167). If you do not specify an address, vim writes the entire contents of the Work buffer. The optional filename is the pathname of the file you are writing to. If you do not specify a filename, vim writes to the file you are editing.

w!

Because the Write command can quickly destroy a large amount of work, vim demands that you enter an exclamation point (!) following the w as a safeguard against accidentally overwriting a file. The only times you do not need an exclamation point are when you are writing out the entire contents of the Work buffer to the file being edited (using no address and no filename) and when you are writing part or all of the Work buffer to a new file. When you are writing part of the file to the file being edited or when you are overwriting another file, you must use an exclamation point.

Identifying the Current File

The File command (:f) provides the same information as the Status command (CONTROL-G, page 171). The filename the File command displays is the one the Write command uses if you give a :w command without a filename.
Setting Parameters

You can tailor the vim editor to your unique needs and habits by setting vim parameters. Parameters perform such functions as displaying line numbers, automatically inserting RETURNs for you, and establishing incremental and nonstandard searches.

You can set parameters in several ways. For example, you can set them to establish the environment for the current editing session while you are using vim. Alternatively, you can set the parameters in your ~/.bash_profile (bash) or ~/.login (tcsh) shell startup file or in the vim startup file, ~/.vimrc. When you set the parameters in any of these files, each time you use vim, the environment has been established and you can begin editing immediately.

Setting Parameters from Within vim

To set a parameter while you are using vim, enter a colon (:), the word set, a SPACE, and the parameter (refer to "Parameters" on page 177). The command appears on the status line as you type it and takes effect when you press RETURN. The following command establishes incremental searches for the current editing session:

```
:set incsearch
```

Setting Parameters in a Startup File

VIMINIT

If you are using bash, you can put a line with the following format in your ~/.bash_profile startup file (page 257):

```
export VIMINIT='set param1 param2 ...
'
```

Replace param1 and param2 with parameters selected from Table 6-7. VIMINIT is a shell variable that vim reads. The following statement ignores the case of characters in searches, displays line numbers, uses the TC Shell to execute Linux commands, and wraps text 15 characters from the right edge of the screen:

```
export VIMINIT='set autoindent number shell=/bin/tcsh wrapmargin=15'
```

Table 6-7. Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Effect</th>
</tr>
</thead>

</tbody>
</table>
### Parameter Effects

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>wrap</td>
<td>set <code>wrap</code> (set by default). If you set <code>nowrap</code>, <code>vim</code> TRuncates long lines at the right edge of the screen.</td>
</tr>
<tr>
<td>Line wrap margin</td>
<td>The line wrap margin causes <code>vim</code> to break the text that you are inserting at approximately the specified number of characters from the right margin. The <code>vim</code> editor breaks the text by inserting a NEWLINE character at the closest blank-delimited word boundary. Setting the line wrap margin is handy if you want all your text lines to be about the same length. It relieves you of having to remember to press RETURN to end each line of input.</td>
</tr>
<tr>
<td><code>wrapmargin= nn</code></td>
<td>Set the parameter <code>wrapmargin= nn</code>, where <code>nn</code> is the number of characters from the right side of the screen where you want <code>vim</code> to break the text. This number is not the column width of the text but the distance from the end of the text to the right edge of the screen. Setting the wrap margin to 0 (zero) turns this feature off. By default the line wrap margin is off (set to 0).</td>
</tr>
<tr>
<td><code>report= nn</code></td>
<td>Causes <code>vim</code> to display a report on the status line whenever you make a change that affects at least <code>nn</code> lines. For example, if <code>report</code> is set to 7 and you delete seven lines, <code>vim</code> displays the message 7 lines deleted. When you delete six or fewer lines, <code>vim</code> does not display a message. The default for <code>report</code> is 5.</td>
</tr>
<tr>
<td><code>scroll= nn</code></td>
<td>Controls the number of lines that <code>CONTROL-D</code> and <code>CONTROL-U</code> (page 158) scroll text on the screen. By default <code>scroll</code> is set to half the window height. There are two ways to change the value of <code>scroll</code>. First you can enter a number before giving a <code>CONTROL-D</code> or <code>CONTROL-U</code> command; <code>vim</code> sets <code>scroll</code> to that number. Alternatively, you can set <code>scroll</code> explicitly with <code>scroll= nn</code>, where <code>nn</code> is the number of lines you want to scroll with each <code>CONTROL-D</code> or <code>CONTROL-U</code> command.</td>
</tr>
<tr>
<td><code>shell= path</code></td>
<td>While you are using <code>vim</code>, you can cause it to spawn a new shell. You can either create an interactive shell (if you want to run several commands) or run a single command. The <code>shell</code> parameter determines which shell <code>vim</code> invokes. By default <code>vim</code> sets the <code>shell</code> parameter to your login shell. To change it, set the parameter <code>shell= path</code>, where <code>path</code> is the absolute pathname of the shell you want to use.</td>
</tr>
<tr>
<td><code>shiftwidth= nn</code></td>
<td>Controls the functioning of <code>CONTROL-T</code> and <code>CONTROL-D</code> in Input mode when automatic indentation is on (see &quot;Automatic indentation&quot; in this table). Set the parameter <code>shiftwidth= nn</code>, where <code>nn</code> is the spacing of the indentation positions (8 by default). Setting the shift width is similar to setting the TAB stops on a typewriter; with <code>shiftwidth</code>, however, the distance between TAB stops remains constant.</td>
</tr>
<tr>
<td><code>showmatch, sm</code></td>
<td>Useful for programmers working in languages that use braces ({}), or parentheses as expression delimiters (Lisp, C, Tcl, and so on). When <code>showmatch</code> is set and you are entering code (in Input mode) and type a closing brace or parenthesis, the cursor jumps briefly to the matching opening brace or parenthesis (that is, the preceding corresponding element at the same nesting level). After it highlights the matching element, the cursor resumes its previous position. When you type a right brace or parenthesis that does not have a match, <code>vim</code> beeps. Use <code>noshowmatch</code> to turn off automatic matching.</td>
</tr>
<tr>
<td><code>showmode, smd</code></td>
<td>Set the parameter <code>showmode</code> to display the mode in the lower-right corner of the screen when <code>vim</code> is in Input mode (default). Set <code>noshowmode</code> to cause <code>vim</code> not to display the mode.</td>
</tr>
</tbody>
</table>
| `vi compatibility`| Refer to "The compatible Parameter" on page 148. By default, except when
### Parameter | Effect
--- | ---
compatible, cp | you have a `.vimrc` startup file (page 176), `vim` attempts to be compatible with `vi`. To cause `vim` to be compatible with `vi`, set the parameter **compatible**. To cause `vim` not to be compatible with `vi`, set the parameter **nocompatible**. Wrap scan | By default, when a search for the next occurrence of a search string reaches the end of the Work buffer, `vim` continues the search at the beginning of the Work buffer. The reverse is true of a search for the previous occurrence of a search string. The **nowrapscan** parameter stops the search at either end of the Work buffer. Set the **wrapscan** parameter if you want searches to wrap around the ends of the Work buffer.

If you use the parameter abbreviations, it looks like this:

```bash
export VIMINIT='set ai nu sh=/bin/tcsh wm=15'
```

If you are using `tcsh`, put the following line in your `~/.tcshrc` startup file (page 342).

```bash
setenv VIMINIT 'set param1 param2 ...
```

Again, replace `param1` and `param2` with parameters from Table 6-7. The values between the single quotation marks are the same as shown in the preceding examples.

### The `.vimrc` Startup File

Instead of setting `vim` parameters in your shell startup file, you can create a `~/.vimrc` file in your home directory and set them there. Creating a `.vimrc` file causes `vim` to start with the **compatible** parameter unset (page 148). Lines in a `.vimrc` file use the following format:

```bash
set param1 param2 ...
```

Following are examples of `.vimrc` files that perform the same function as `VIMINIT` described previously:

```bash
$ cat ~/.vimrc
set ignorecase
set number
set shell=/bin/tcsh
set wrapmargin=15
```
$ cat ~/.vimrc

set ic nu sh=/bin/tcsh wm=15

Parameters set by the VIMINIT variable take precedence over those set in the .vimrc file.

Parameters

Table 6-7 lists some of the most useful vim parameters. The vim editor displays a complete list of parameters and indicates how they are currently set when you give the command :set all followed by a RETURN. The command :set RETURN displays a list of options that are set to values other than their default values. Two classes of parameters exist: those that contain an equal sign (and can take on a value) and those that are optionally prefixed with no (switches that are on or off). You can change the sense of a switch parameter by giving the command :set [no] param. For example, give the command :set number (or :set nonumber) to turn on (or off) line numbering. To change the value of a parameter that takes on a value (and uses an equal sign), give a command such as :set shiftwidth=15.

Most parameters have abbreviations such as nu for number, nonu for no number, and sw for shiftwidth. The abbreviations are listed in the left column of Table 6-7, following the name of the parameter.
Advanced Editing Techniques

This section presents several commands that you may find useful once you have become comfortable using \texttt{vim}.
optional: Using Markers

While you are using `vim`, you can set and use markers to make addressing more convenient. Set a marker by giving the command `m c`, where `c` is any character. (Letters are preferred because some characters, such as a single quotation mark, have special meanings when used as markers.) The `vim` editor does not preserve markers when you exit from `vim`.

Once you have set a marker, you can use it in a manner similar to a line number. You can move the cursor to the beginning of a line that contains a marker by preceding the marker name with a single quotation mark. For example, to set marker `t`, position the cursor on the line you want to mark and give the command `mt`. During this editing session, unless you reset marker `t` or delete the line it marks, you can return to the beginning of the line you marked with the command `''t`.

You can delete all text from the current line through the line containing marker `r` with the following command:

```
d'r
```

You can use a back tick (``, also called a grave accent or reverse single quotation mark) to go to the exact position of the mark on the line. After setting marker `t`, you can move the cursor to the location of this marker (not the beginning of the line that holds the marker) with the command `''t`. The following command deletes all the text from the current line up to the character where the mark `r` was placed; the rest of the line containing the marker remains intact:

```
d'r
```

You can use markers in addresses of commands instead of line numbers. The following command replaces all occurrences of `The` with `THE` on all lines from marker `m` to the current line (marker `m` must precede the current line):

```
:m,.s/The/THE/g
```

EDITING OTHER FILES

The following command causes `vim` to edit the file you specify with `filename`:

```
:e[!] [filename]
```

If you want to save the contents of the Work buffer, you must write it out (using `:w`) before you give this command. If you do not want to save the contents of the Work buffer, `vim` insists that you use an exclamation point to acknowledge that you will lose the work you did since the last time you wrote out the Work buffer. If you do not supply a `filename`, `vim` edits the same file you are currently working
The Work buffer. If you do not supply a filename, vim edits the same file you are currently working on.

The command :e! starts an editing session over again. This command returns the Work buffer to the state it was in the last time you wrote it out or, if you have not written it out, the state it was in when you started editing the file. It is useful when you make mistakes while editing a file and decide that it would be easier to start over than to fix the mistakes.

Because this command does not destroy the contents of the General-Purpose or Named buffers, you can store text from one file in a buffer, use a :e command to edit a second file, and put text from the buffer in the second file.

:e#

The command :e# closes the current file and opens the last file you were editing, placing the cursor on the line that it was on when you last closed the file. If you do not save the file you are working on before you give this command, vim prompts you to do so. Setting the autowrite parameter (page 178) will not stop vim from prompting you.

:n

:rew

The :e# command can help you copy blocks of text from one file to another. Call vim with the names of several files as arguments. You can use :n to edit the next file, :e# to edit the file you just edited, and :rew to rewind the sequence of files so that you are editing the first file again. As you move between files, you can copy text from one file into a buffer and paste that text into another file. You can use :n! to force vim to close a file without writing out changes before it opens the next file.

MACROS AND SHORTCUTS

:map

The vim editor allows you to create macros and shortcuts. The :map command defines a key or sequence of keys that perform some action in Command mode. The following command maps CONTROL-X to the commands that will find the next left bracket on the line the cursor is on (f[), delete all characters from that bracket to the next right bracket (df) on the same line, delete the next character (x), move the cursor down two lines (2j), and finally move the cursor to the beginning of the line (0):

    :map ^X f[df]x2j0

You can use ESCAPE and CONTROL sequences but try to avoid remapping characters or sequences that are vim commands. Type :map by itself to see a list of the current mappings. You may need to use CONTROL-V (page 159) to quote some of the characters you want to enter into the :map string.

:abbrev

The :abbrev command is similar to :map but creates abbreviations you can use while in Input mode. When you are in Input mode and type a string you have defined with :abbrev, followed by a SPACE,
When you are in Input mode and type a string you have defined with \texttt{:abbrev}, followed by a SPACE, \texttt{vim} replaces the string and the SPACE with the characters you specified when you defined the string. For ease of use, do not use common sequences of characters when creating abbreviations. The following command defines \texttt{ZZ} as an abbreviation for \textbf{Mark G. Sobell}:

\begin{verbatim}
:abbrev ZZ Mark G. Sobell
\end{verbatim}

Even though \texttt{ZZ} is a \texttt{vim} command, it is used only in Command mode. It has no special meaning in Input mode, where you use abbreviations.

**Executing Shell Commands from Within \texttt{vim}**

You can execute shell commands in several ways while you are using \texttt{vim}. You can spawn a new interactive shell by giving the following command and pressing RETURN:

\begin{verbatim}
:sh
\end{verbatim}

The \texttt{vim shell} parameter (page 179) determines which shell is spawned (usually \texttt{bash} or \texttt{tcsh}). By default \texttt{shell} is the same as your login shell.

After you have finished your work in the shell, you can return to \texttt{vim} by exiting from the shell (press CONTROL-D or give an \texttt{exit} command).

\begin{verbatim}
tip: If \texttt{:sh} does not work correctly
\end{verbatim}

The \texttt{:sh} command may behave strangely depending on how your shell has been configured. You may get warnings with the \texttt{:sh} command or it may even hang. Experiment with the \texttt{:sh} command to be sure it works with your configuration. If it does not, then you might want to set the \texttt{vim shell} parameter to another shell before using \texttt{:sh}. For example, the following command causes \texttt{vim} to use \texttt{tcsh} with the \texttt{:sh} command:

\begin{verbatim}
:set shell=/bin/tcsh
\end{verbatim}

You may need to change the \texttt{SHELL} environment variable after starting \texttt{:sh} to show the correct shell.

**caution: Edit only one copy of a file**

When you create a new shell by using \texttt{:sh}, remember that you are still using \texttt{vim}. A common mistake is to try to edit the same file from the new shell, forgetting that \texttt{vim} is already editing the file from a different shell. Because you can lose information by editing the same file from two instances of an editor, \texttt{vim} warns you when you make this mistake. Refer to "File Locks" on page 152 to see an example of the message that \texttt{vim} displays.

You can execute a shell command line from \texttt{vim} by giving the following command, replacing \texttt{command} with the command line you want to execute and terminating the command with a RETURN:

\begin{verbatim}
:!command
\end{verbatim}
The `vim` editor spawns a new shell that executes the `command`. When the `command` runs to completion, the newly spawned shell returns control to the editor.

You can execute a command from `vim` and have it replace the current line with the output from the command. If you do not want to replace any text, put the cursor on a blank line before giving the following command:

```
!!command
```

Nothing happens when you enter the first exclamation point. When you enter the second one, `vim` moves the cursor to the status line and allows you to enter the command you want to execute. Because this command puts `vim` in Last Line mode, you must end the command with a RETURN (as you would end most shell commands).

Finally you can execute a command from `vim` with standard input to the command coming from all or part of the file you are editing and standard output from the command replacing the input in the file you are editing. You can use this type of command to sort a list in place within a file.

To specify the block of text that will become standard input for the command, move the cursor to one end of the block of text. Then enter an exclamation point followed by a command that would normally move the cursor to the other end of the block of text. For example, if the cursor is at the beginning of the file and you want to specify the whole file, give the command `!G`. If you want to specify the part of the file between the cursor and marker `b`, give the command `!'b`. After you give the cursor-movement command, `vim` displays an exclamation point on the status line and waits for you to enter a shell command.

To sort a list of names in a file, move the cursor to the beginning of the list and set marker `q` with an `mq` command. Then move the cursor to the end of the list and give the following command:

```
!'sort
```

Press RETURN and wait. After a few seconds, the sorted list should replace the original list on the screen. If the command did not do what you expected, you can usually undo the change with a `u` command. Refer to page 762 for more information on `sort`.

**caution: `!` can destroy a file**

If you enter the wrong command or mistype a command, you can destroy a file (for example, if the command hangs or stops `vim` from working). For this reason it is a good idea to save your file before using this command. The Undo command (page 160) can be a lifesaver. A `:e!` command (page 181) will get rid of your changes, returning the buffer to the state it was in last time you saved it.

As with the `:sh` command, the default shell may not work properly with the `!` command. You may want to test the shell with a simple file before executing this command with your real work. If the usual shell does not work properly, change the `shell` parameter.
Units of Measure

Many vim commands operate on a block of text ranging from one character to many paragraphs. You specify the size of a block of text with a Unit of Measure. You can specify multiple Units of Measure by preceding a Unit of Measure with a Repeat Factor (page 187). This section defines the various Units of Measure.

Character

A character is one character—visible or not, printable or not—including SPACEs and TABs. Some examples of characters are

\[ a \ q \ A \ . \ R \ - \ > \ TAB \ SPACE \]

Word

A word, similar to an ordinary word in the English language, is a string of one or more characters bounded on both sides by any combination of one or more of the following elements: a punctuation mark, SPACE, TAB, numeral, or NEWLINE. In addition, vim considers each group of punctuation marks to be a word (Table 6-8).

<table>
<thead>
<tr>
<th>Word count</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>pear</td>
</tr>
<tr>
<td>2</td>
<td>pear!</td>
</tr>
<tr>
<td>2</td>
<td>pear! )</td>
</tr>
<tr>
<td>3</td>
<td>pear! ) The</td>
</tr>
<tr>
<td>4</td>
<td>pear! ) &quot;The</td>
</tr>
<tr>
<td>11</td>
<td>This is a short, concise line (no frills).</td>
</tr>
</tbody>
</table>

Blank-Delimited Word

A blank-delimited word is the same as a word but includes adjacent punctuation. Blank-delimited words are separated by one or more of the following elements: a SPACE, TAB, or NEWLINE (Table 6-9).

<table>
<thead>
<tr>
<th>Word count</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>pear</td>
</tr>
<tr>
<td>1</td>
<td>pear!</td>
</tr>
<tr>
<td>1</td>
<td>pear! )</td>
</tr>
<tr>
<td>2</td>
<td>pear! ) The</td>
</tr>
<tr>
<td>2</td>
<td>pear! ) &quot;The</td>
</tr>
<tr>
<td>8</td>
<td>This is a short, concise line (no frills).</td>
</tr>
</tbody>
</table>
Line

A line is a string of characters bounded by NEWLINEs that is not necessarily displayed as a single physical line on the screen. You can enter a very long single (logical) line that wraps around (continues on the next physical line) several times or disappears off the right edge of the display. It is a good idea to avoid long logical lines by terminating lines with a RETURN before they reach the right side of the screen. Terminating lines in this manner ensures that each physical line contains one logical line and avoids confusion when you edit and format text. Some commands do not appear to work properly on physical lines that are longer than the width of the screen. For example, with the cursor on a long logical line that wraps around several physical lines, pressing RETURN once appears to move the cursor down more than one line. You can use fmt (page 664) to break long logical lines into shorter ones.

Sentence

A sentence is an English sentence or the equivalent. A sentence starts at the end of the previous sentence and ends with a period, exclamation point, or question mark, followed by two SPACEs or a NEWLINE (Table 6-10).

Table 6-10. Sentences

<table>
<thead>
<tr>
<th>Sentence count</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>One: only one SPACE after the first period and a NEWLINE after the second period</td>
<td>That's it. This is one sentence.</td>
</tr>
<tr>
<td>Two: two SPACEs after the first period and a NEWLINE after the second period</td>
<td>That's it. This is two sentences.</td>
</tr>
<tr>
<td>Three: two SPACEs after the first two question marks and a NEWLINE after the exclamation point</td>
<td>What? Three sentences? One line!</td>
</tr>
<tr>
<td>One: NEWLINE after the period</td>
<td>This sentence takes up a total of three lines.</td>
</tr>
</tbody>
</table>

Paragraph

A paragraph is preceded and followed by one or more blank lines. A blank line is composed of two NEWLINE characters in a row (Table 6-11).

Table 6-11. Paragraphs

<table>
<thead>
<tr>
<th>Paragraph count</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>One: blank line before and after text</td>
<td>One paragraph</td>
</tr>
<tr>
<td>One: blank line before and after text</td>
<td>This may appear to be</td>
</tr>
</tbody>
</table>
Paragraph count

Text

more than one paragraph.

Just because there are
two indentions does not mean
it qualifies as two paragraphs.

Three: three blocks of text separated by blank lines

Even though in

English this is only
one sentence,

vim considers it to be
three paragraphs.

Window

Under vim, a screen or terminal emulator window can display one or more logical windows of information. A window displays all or part of a Work buffer. Figure 6-5 on page 145 shows a screen with two windows.

Repeat Factor

A number that precedes a Unit of Measure (page 184) is a Repeat Factor. Just as the 5 in 5 inches causes you to consider 5 inches as a single Unit of Measure, so a Repeat Factor causes vim to group more than one Unit of Measure and consider it as a single Unit of Measure. For example, the command w moves the cursor forward 1 word, the command 5w moves it forward 5 words, and the command 250w moves it forward 250 words. If you do not specify a Repeat Factor, vim assumes a Repeat Factor of 1. If the Repeat Factor would move the cursor past the end of the file, the cursor is left at the end of the file.
Chapter Summary

This summary of `vim` includes all the commands covered in this chapter, plus a few more. Table 6-12 lists some of the ways you can call `vim` from the command line.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>vim filename</code></td>
<td>Edits <code>filename</code> starting at line 1</td>
</tr>
<tr>
<td><code>vim + n filename</code></td>
<td>Edits <code>filename</code> starting at line n</td>
</tr>
<tr>
<td><code>vim + filename</code></td>
<td>Edits <code>filename</code> starting at the last line</td>
</tr>
<tr>
<td><code>vim +/- pattern filename</code></td>
<td>Edits <code>filename</code> starting at the first line containing <code>pattern</code></td>
</tr>
<tr>
<td><code>vim r filename</code></td>
<td>Recovers <code>filename</code> after a system crash</td>
</tr>
<tr>
<td><code>vim R filename</code></td>
<td>Edits <code>filename</code> readonly (same as opening the file with <code>view</code>)</td>
</tr>
</tbody>
</table>

You must be in Command mode to use commands that move the cursor by Units of Measure (Table 6-13). You can use these Units of Measure with Change, Delete, and Yank commands. Each of these commands can be preceded by a Repeat Factor.

<table>
<thead>
<tr>
<th>Command</th>
<th>Moves the cursor</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPACE, l (ell), or RIGHT ARROW</td>
<td>Space to the right</td>
</tr>
<tr>

<th>Moves the cursor</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-D</td>
<td>Forward one-half window</td>
</tr>
<tr>
<td>CONTROL-U</td>
<td>Backward one-half window</td>
</tr>
<tr>
<td>CONTROL-F or PAGE DOWN</td>
<td>Forward one window</td>
</tr>
<tr>
<td>CONTROL-B or PAGE UP</td>
<td>Backward one window</td>
</tr>
<tr>
<td>n G</td>
<td>To line n (without n, to the last line)</td>
</tr>
<tr>
<td>H</td>
<td>To top of window</td>
</tr>
<tr>
<td>M</td>
<td>To middle of window</td>
</tr>
<tr>
<td>L</td>
<td>To bottom of window</td>
</tr>
</tbody>
</table>

The commands in Table 6-15 enable you to add text to the buffer. All these commands, except r, leave vim in Input mode. You must press ESCAPE to return to Command mode.

Table 6-15. Adding text

<table>
<thead>
<tr>
<th>Command</th>
<th>Adds text</th>
</tr>
</thead>
<tbody>
<tr>
<td>i</td>
<td>Before cursor</td>
</tr>
<tr>
<td>I</td>
<td>Before first nonblank character on line</td>
</tr>
<tr>
<td>a</td>
<td>After cursor</td>
</tr>
<tr>
<td>A</td>
<td>At end of line</td>
</tr>
<tr>
<td>o</td>
<td>Open a line below current line</td>
</tr>
<tr>
<td>O</td>
<td>Open a line above current line</td>
</tr>
<tr>
<td>r</td>
<td>Replace current character (no ESCAPE needed)</td>
</tr>
<tr>
<td>R</td>
<td>Replace characters, starting with current character (overwrite until ESCAPE)</td>
</tr>
</tbody>
</table>

Table 6-16 lists commands that delete and change text. In this table M is a Unit of Measure that you can precede with a Repeat Factor, n is an optional Repeat Factor, and c is any character.

Table 6-16. Deleting and changing text

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>n x</td>
<td>Deletes the number of characters specified by n, starting with the current character</td>
</tr>
<tr>
<td>n X</td>
<td>Deletes n characters before the current character, starting with the character preceding the current character</td>
</tr>
<tr>
<td>d M</td>
<td>Deletes text specified by M</td>
</tr>
<tr>
<td>n dd</td>
<td>Deletes n lines</td>
</tr>
<tr>
<td>dt c</td>
<td>Deletes to the next character c on the current line</td>
</tr>
<tr>
<td>D</td>
<td>Deletes to end of the line</td>
</tr>
<tr>
<td>n~</td>
<td>Change case of the next n characters</td>
</tr>
</tbody>
</table>

The following commands leave vim in Input mode. You must press ESCAPE to return to Command mode.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>n s</td>
<td>Substitutes n characters</td>
</tr>
<tr>
<td>S</td>
<td>Substitutes for the entire line</td>
</tr>
</tbody>
</table>
Table 6-17 lists search commands. Here *rexp* is a regular expression that can be a simple string of characters.

### Table 6-17. Searching

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>/rexpRETURN</td>
<td>Searches forward for <em>rexp</em></td>
</tr>
<tr>
<td>?rexpRETURN</td>
<td>Searches backward for <em>rexp</em></td>
</tr>
<tr>
<td>n</td>
<td>Repeats original search exactly</td>
</tr>
<tr>
<td>N</td>
<td>Repeats original search, in the opposite direction</td>
</tr>
<tr>
<td>/RETURN</td>
<td>Repeats original search forward</td>
</tr>
<tr>
<td>?RETURN</td>
<td>Repeats original search backward</td>
</tr>
<tr>
<td>fc</td>
<td>Positions the cursor on the next character <em>c</em> on the current line</td>
</tr>
<tr>
<td>Fc</td>
<td>Positions the cursor on the previous character <em>c</em> on the current line</td>
</tr>
<tr>
<td>tc</td>
<td>Positions the cursor on the character before (to the left of) the next character <em>c</em> on the current line</td>
</tr>
<tr>
<td>Tc</td>
<td>Positions the cursor on the character after (to the right of) the previous character <em>c</em> on the current line</td>
</tr>
<tr>
<td>;</td>
<td>Repeats the last <em>f, F, t</em>, or <em>T</em> command</td>
</tr>
</tbody>
</table>

The format of a Substitute command is

```
: [address]s/rexp/replacement-string[/g]
```

where *address* is one line number or two line numbers separated by a comma. A . (period) represents the current line, $ represents the last line, and % represents the entire file. You can use a marker or a search string in place of a line number. The *search-string* is a regular expression that can be a simple string of characters. The *replacement-string* is the replacement string. A *g* indicates a global replacement (more than one replacement per line).

Table 6-18 lists miscellaneous vim commands.

### Table 6-18. Miscellaneous commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>J</td>
<td>Joins the current line and the following line</td>
</tr>
<tr>
<td>.</td>
<td>Repeats the most recent command that made a change</td>
</tr>
<tr>
<td>:w filename</td>
<td>Writes contents of Work buffer to <em>filename</em> (or to current file if there is no <em>filename</em>)</td>
</tr>
<tr>
<td>:q</td>
<td>Quits vim</td>
</tr>
</tbody>
</table>
Table 6-19 lists commands that yank and put text. In this table \textit{M} is a Unit of Measure that you can precede with a Repeat Factor and \textit{n} is a Repeat Factor. You can precede any of these commands with the name of a buffer using the form \texttt{"x}, where \texttt{x} is the name of the buffer (\texttt{az}).

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{y M}</td>
<td>Yanks text specified by \textit{M}</td>
</tr>
<tr>
<td>\texttt{nn}</td>
<td>Yanks \textit{n} lines</td>
</tr>
<tr>
<td>\texttt{Y}</td>
<td>Yanks to end of line</td>
</tr>
<tr>
<td>\texttt{P}</td>
<td>Puts text before or above</td>
</tr>
<tr>
<td>\texttt{p}</td>
<td>Puts text after or below</td>
</tr>
</tbody>
</table>

Table 6-20 lists advanced \texttt{vim} commands.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{m x}</td>
<td>Sets marker \texttt{x}, where \texttt{x} is a letter from \texttt{a} to \texttt{z}.</td>
</tr>
<tr>
<td>\texttt{''} (two single quotation marks)</td>
<td>Moves cursor back to its previous location.</td>
</tr>
<tr>
<td>\texttt{'} \texttt{x}</td>
<td>Moves cursor to line with marker \texttt{x}.</td>
</tr>
<tr>
<td>\texttt{'} \texttt{x}</td>
<td>Moves cursor to character with marker \texttt{x}.</td>
</tr>
<tr>
<td>\texttt{:e filename}</td>
<td>Edits \texttt{filename}, requiring you to write out changes to the current file (with \texttt{:w} or \texttt{autowrite}) before editing the new file. Use \texttt{:e! filename} to discard changes to the current file. Use \texttt{:e!} without a filename to discard changes to the current file and start editing the saved version of the current file.</td>
</tr>
<tr>
<td>\texttt{:n}</td>

Exercises

1. How can you cause vim to enter Input mode? How can you make vim revert to Command mode?

2. What is the Work buffer? Name two ways of writing the contents of the Work buffer to the disk.

3. Suppose that you are editing a file that contains the following paragraph and the cursor is on the second tilde (~):

   The vim editor has a command, tilde (~),
   that changes lowercase letters to
   uppercase, and vice versa.

   The ~ command works with a Unit of Measure or
   a Repeat Factor, so you can change
   the case of more than one character at a time.

   How can you
   
   a. Move the cursor to the end of the paragraph?
   b. Move the cursor to the beginning of the word Unit?
   c. Change the word character to letter?

4. While working in vim, with the cursor positioned on the first letter of a word, you give the command x followed by p. Explain what happens.

5. What are the differences between the following commands?
   
   a. i and I
   b. a and A
   c. o and O
   d. r and R
   e. u and U

6. Which command would you use to search backward through the Work buffer for lines that start
with the word it?

7. Which command substitutes all occurrences of the phrase **this week** with the phrase **next week**?

8. Consider the following scenario: You start **vim** to edit an existing file. You make many changes to the file and then realize that you deleted a critical section of the file early in your editing session. You want to get that section back but do not want to lose all the other changes you made. What would you do?

9. How can you move the line that the cursor is on to the beginning of the file?

10. Use **vim** to create the **letter_e** file of e's used on page 56. Use as few **vim** commands as possible. Which **vim** commands did you use?
Advanced Exercises

11. Which commands can you use to take a paragraph from one file and insert it in a second file?

12. Create a file that contains the following list, and then execute commands from within `vim` to sort the list and display it in two columns. *(Hint: Refer to page 744 for more information on `pr`)*

   **Command mode**
   **Input mode**
   **Last Line mode**
   **Work buffer**
   **General-Purpose buffer**
   **Named buffer**
   **Regular Expression**
   **Search String**
   **Replacement String**
   **Startup File**
   **Repeat Factor**

13. How do the Named buffers differ from the General-Purpose buffer?

14. Assume that your version of `vim` does not support multiple Undo commands. If you delete a line of text, then delete a second line, and then a third line, which commands would you use to recover the first two lines that you deleted?

15. Which command would you use to swap the words `hither` and `yon` on any line with any number of words between them? *(You need not worry about special punctuation, just uppercase and lowercase letters and spaces.)*
In 1956 the Lisp (List processing) language was developed at MIT by John McCarthy. In its original conception, Lisp had only a few scalar (atomic) data types and only one data structure (page 870): a list. Lists could contain atomic data or perhaps other lists. Lisp supported recursion and nonnumeric data (exciting concepts in those FORTRAN and COBOL days) and, in the Cambridge culture at least, was once the favored implementation language. Richard Stallman and Guy Steele were part of this MIT Lisp culture. In 1975 they collaborated on emacs, which Stallman maintained by himself for a long time. This chapter discusses the emacs editor as implemented by the Free Software Foundation (GNU). The emacs home page is www.gnu.org/software/emacs.
History

The `emacs` editor was prototyped as a series of extension commands or macros for the late 1960s text editor TECO (Text Editor and CORrector). Its acronymic name, Editor MACroS, reflects this origin, although there have been many humorous reinterpretations, including ESCAPE META ALT CONTROL SHIFT, Emacs Makes All Computing Simple, and the unkind translation Eight Megabytes And Constantly Swapping.

Evolution

Over time `emacs` has grown and evolved through more than 20 major revisions to the mainstream GNU version. The `emacs` editor, which is coded in C, contains a complete Lisp interpreter and fully supports the X Window System and mouse interaction. The original TECO macros are long gone, but `emacs` is still very much a work in progress. There are plans to support variable-width fonts, wide character sets, and the world's major languages as well as to move `emacs` in the direction of a WYSIWYG (what you see is what you get) word processor and make it easier for beginners to use.

The `emacs` editor has always been considerably more than a text editor. Not having been developed originally in a UNIX environment, it does not adhere to the UNIX/Linux philosophy. Whereas a UNIX/Linux utility is typically designed to do one thing and to be used in conjunction with other utilities, `emacs` is designed to "do it all." Taking advantage of the underlying programming language (Lisp), `emacs` users tend to customize and extend the editor rather than to use existing utilities or create new general-purpose tools. Instead they share their `~/.emacs` (customization) files.

Well before the emergence of the X Window System, Stallman put a great deal of thought and effort into designing a window-oriented work environment, and he used `emacs` as his research vehicle. Over time he built facilities within `emacs` for reading and composing email messages, reading and posting netnews, giving shell commands, compiling programs and analyzing error messages, running and debugging these programs, and playing games. Eventually it became possible to enter the `emacs` environment and not come out all day, switching from window to window and from file to file. If you had only an ordinary serial, character-based terminal, `emacs` gave you tremendous leverage.

In an X Window System environment, `emacs` does not need to control the whole display. Instead, it usually operates only one or two windows. The original work environment is still available and is covered in this chapter.

As a language-sensitive editor, `emacs` has special features that you can turn on to help edit text, `nroff`, TeX, Lisp, C, Fortran, and so on. These feature sets are called modes, but they are not related in any way to the Command mode and Input mode found in `vi`, `vim`, and other editors. Because you never need to switch `emacs` between Input and Command modes, `emacs` is a modeless editor.

`emacs` Versus `vim`

Like `vim`, `emacs` is a display editor: It displays on the screen the text you are editing and changes the display as you type each command or insert new text. Unlike `vim`, `emacs` does not require you to keep track of whether you are in Command mode or Insert mode: Commands always use CONTROL or other special keys. The `emacs` editor inserts ordinary characters into the text you are editing (as opposed to using ordinary characters as commands), another trait of modeless editing. For many people this approach is convenient and natural.

Like `vim`, `emacs` has a rich, extensive command set for moving about in the buffer and altering text. This command set is not "cast in concrete"—you can change or customize commands at any time. Literally any key can be coupled (bound) to any command so as to match a particular keyboard better or just to fulfill a personal whim. Usually key bindings are set in the `emacs` startup file, but they can also be changed interactively during a session.
All the key bindings described in this chapter are standard on current GNU emacs versions, which also support many visual, mouse-oriented capabilities that are not covered here.

**caution: Too many key bindings**

If you change too many key bindings, you may produce a command set that you will not remember or that will make it impossible for you to get back to the standard bindings again in the same session.

Finally, and very unlike vim, emacs allows you to use Lisp to write new commands or override old ones. Stallman calls this feature online extensibility, but it would take a gutsy Lisp guru to write and debug a new command while editing live text. It is much more common to add a few extra debugged commands to the .emacs file, where they are loaded when emacs starts up. Experienced emacs users often write modes, or environments, that are conditionally loaded by emacs for specific tasks.

**tip: The screen and emacs windows**

In this chapter, the term *screen* denotes a character-based terminal screen or a terminal emulator window in a graphical environment. The term *window* refers to an emacs window within a screen.

**tip: emacs and the X Window System**

With version 19, GNU emacs fully embraced the X Window System environment. If you start emacs from a terminal emulator window running in a graphical environment, you will bring up the X (GUI) interface to emacs. This book does not cover the graphical interface; use the `nw` option when you start emacs to bring up the textual interface in any environment. See "Starting emacs" on page 198.
Tutorial: Getting Started with emacs

The emacs editor has many, many features, and there are many ways to use it. Its complete manual includes more than 35 chapters. Nevertheless, you can do a considerable amount of meaningful work with a relatively small subset of the commands. This section describes a simple editing session, explaining how to start and exit from emacs and how to move the cursor and delete text. Some issues are postponed or simplified in the interest of clarity.

Starting emacs

To edit a file named sample using emacs as a text-based editor, enter the following command. The \texttt{-nw} option, which must be the first option on the \texttt{emacs} command line, tells \texttt{emacs} not to use its X (GUI) interface.

\$ emacs -nw -q sample

This command starts emacs, reads the file named sample into a buffer, and displays its contents on the screen or window. If no file has this name, emacs displays a blank screen with New File at the bottom (Figure 7-1). If the file exists, emacs displays another message (Figure 7-2, page 200). The \texttt{-q} option tells emacs not to read the \texttt{~/.emacs} startup file from your home directory. Not reading the startup file guarantees that you get standard, uncustomized behavior and is sometimes useful for beginners or for other users who want to bypass a \texttt{.emacs} file.

Figure 7-1. The emacs welcome screen

[View full size image]
The screen starts with a single window. At the bottom of this window is a reverse-video titlebar called the Mode Line. At a minimum, the Mode Line shows which buffer the window is viewing, whether the buffer has been changed, what major and minor modes are in effect, and how far down the buffer the window is positioned. When you have more than one window, one Mode Line appears in each window. At the bottom of the screen, emacs leaves a single line open. This Echo Area, or Minibuffer, line is used for short messages and special one-line commands.

A cursor is in the window or Minibuffer. All input and nearly all editing takes place at the cursor. As you type ordinary characters, emacs inserts them at the cursor position. If characters are under the cursor or to its right, they get pushed to the right as you type, so no characters are lost.

Stopping emacs

The command to exit from emacs is the two-key sequence CONTROL-X CONTROL-C. You can give this command at almost any time (in some modes you may have to press CONTROL-G first). It stops emacs gracefully, asking you to confirm changes if you made any during the editing session.

If you want to cancel a half-typed command or stop a running command before it is done, you can quit by pressing CONTROL-G. The emacs editor displays Quit in the Echo Area and waits for your next command.

Inserting Text

Typing an ordinary (printing) character pushes the cursor and any characters to the right of the cursor one position to
the right and inserts the new character in the position just opened. Backspacing pulls the cursor and any characters
to the right of the cursor one position to the left, erasing the character that was there before.

Deleting Characters

Depending on the keyboard you are using and the emacs startup file, different keys may delete characters in
different ways. CONTROL-D typically deletes the character under the cursor, as do DELETE and DEL.
BACKSPACE typically deletes the character to the left of the cursor. Try each of these keys and see what it does.

**tip: More about deleting characters**

If the instructions described in this section do not work, read the emacs info section on deletion.
Give this command from a shell prompt:

```
$ info emacs
```

From info give the command m deletion to display a document that describes in detail how to delete
small amounts of text. Use the SPACE bar to scroll through the document. Type q to exit from info.

Start emacs and type a few lines of text. If you make a mistake, use the deletion characters discussed previously.
The RETURN key inserts an invisible end-of-line character in the buffer and returns the cursor to the left margin,
one line down. It is possible to back up past the start of a line and up to the end of the previous line. Figure 7-2
shows a sample buffer.

Moving the Cursor

You can position the cursor over any character in the emacs window and move the window so it displays any
portion of the buffer. You can move the cursor forward or backward through the text (Figure 6-8, page 155) by
various textual units—for example, characters, words, sentences, lines, and paragraphs. Any of the cursor-movement
commands can be preceded by a repetition count (CONTROL-U followed by a numeric argument), which causes
the cursor to move that number of textual units through the text. Refer to page 205 for a discussion of numeric
arguments.

**tip: Use the ARROW keys**

Sometimes the easiest way to move the cursor is by using the LEFT, RIGHT, UP, and DOWN ARROW
keys.

Moving the Cursor by Characters

**CONTROL-F**

Pressing the RIGHT ARROW key or CONTROL-F moves the cursor forward one character. If the cursor is at the
end of a line, these commands wrap it to the beginning of the next line. The command CONTROL-U 7 CONTROL-F moves the cursor seven characters forward (to the right).
**CONTROL-B**

Pressing the LEFT ARROW key or CONTROL-B moves the cursor backward one character. The command CONTROL-U 7 CONTROL-B moves the cursor seven characters backward (to the left). CONTROL-B works in a manner similar to CONTROL-F (Figure 7-3).

![Figure 7-3. Moving the cursor by characters](image)

**Moving the Cursor by Words**

**META-f**

Pressing META-f moves the cursor forward one word. To press META-f hold down the META or ALT key while you press f. If you do not have either of these keys, press ESCAPE, release it, and then press f. This command leaves the cursor on the first character that is not part of the word the cursor started on. The command CONTROL-U 4 META-f moves the cursor forward one space past the end of the fourth word. See page 204 for more about keys.

**META-b**

Pressing META-b moves the cursor backward one word so the cursor is on the first letter of the word it started on. If the cursor was on the first letter of a word, META-b moves the cursor to the first letter of the preceding word. It works in a manner similar to META-f (Figure 7-4).

![Figure 7-4. Moving the cursor by words](image)

**Moving the Cursor by Lines**

**CONTROL-A CONTROL-E**  
**CONTROL-P CONTROL-N**

Pressing CONTROL-A moves the cursor to the beginning of the line it is on; CONTROL-E moves it to the end. Pressing the UP ARROW key or CONTROL-P moves the cursor up one line to the position directly above where
the cursor started; the DOWN ARROW key or CONTROL-N moves it down. As with the other cursor-movement keys, you can precede CONTROL-P and CONTROL-N with CONTROL-U and a numeric argument to move up or down multiple lines. You can use pairs of these commands to move the cursor up to the beginning of the previous line, down to the end of the following line, and so on (Figure 7-5).

Figure 7-5. Moving the cursor by lines

Moving the Cursor by Sentences, Paragraphs, and Window Position

META-a, META-e META-{, META-}

Pressing META-a moves the cursor to the beginning of the sentence the cursor is on; META-e moves the cursor to the end. META-{ moves the cursor to the beginning of the paragraph the cursor is on; META-} moves it to the end. (Sentences and paragraphs are defined starting on page 227.) You can precede any of these commands with a repetition count (CONTROL-U and a numeric argument) to move the cursor that many sentences or paragraphs.

META-r

Pressing META-r moves the cursor to the beginning of the middle line of the window. You can precede this command with CONTROL-U and a line number (here CONTROL-U does not indicate a repetition count but a screen line number). The command CONTROL-U 0 META-r moves the cursor to the beginning of the top line (line zero) in the window. You can replace zero with the line number of the line you want to move the cursor to or with a minus sign (\(-\)) in which case the cursor moves to the beginning of the last line of the window (Figure 7-6).

Figure 7-6. Moving the cursor by sentences, paragraphs, and window position

[View full size image]
Editing at the Cursor Position

With the cursor in the window you can type new text, pushing the existing text to the right. Entering new text requires no special commands once the cursor is positioned. If you type so many characters that the text in a line goes past the right edge of the window, Emacs puts a backslash (\) near the right edge of the window and wraps the text to the next line. The backslash appears on the screen but is not saved as part of the file and is never printed. Although you can create an arbitrarily long line, some UNIX tools have problems with text files containing such lines. You can split a line at any point by positioning the cursor and pressing RETURN.

Deleting text

Pressing DELETE removes characters to the left of the cursor. The cursor and the remainder of the text on this line both move to the left each time you press DELETE. To join a line with the line above it, position the cursor on the first character of the second line and press DELETE.

Press CONTROL-D to delete the character under the cursor. The cursor remains stationary, but the remainder of the text on the line moves left to replace the deleted character. See the tip "More about deleting characters" on page 199 if either of these keys does not work as described here.

Saving and Retrieving the Buffer

No matter what happens to a buffer during an Emacs session, the associated file does not change until you save the buffer. If you leave Emacs without saving the buffer (this is possible if you are insistent enough), the file is not changed and the session's work is discarded.

Backups

As mentioned previously, Emacs prompts you about unsaved changes to the buffer contents. As it writes a buffer's
edited contents back to the file, **emacs** may optionally first make a backup of the original file contents. You can choose to make no backups, one level (default), or an arbitrary number of levels. The one-level backup filenames are formed by appending a ~ character to the original filename. The multilevel backups append \texttt{~n~} to the filename, where \texttt{n} is the sequential backup number, starting with 1. The **version-control** variable dictates how **emacs** saves backups.

Saving the buffer

The command CONTROL-X CONTROL-S saves the current buffer in its associated file. The **emacs** editor confirms a successful save with a message in the Echo Area.

Visiting another file

If you are already editing a file with **emacs** and want to edit another file (also called visiting a file), you can copy the new file into a new **emacs** buffer by giving the command CONTROL-X CONTROL-F. The **emacs** editor prompts you for a filename, reads that file into a new buffer, and displays that buffer in the current window. Having two files open in one editing session is more convenient than exiting from **emacs**, returning to the shell, and then starting a new copy of **emacs** to edit a second file.

**tip: Visiting a file with CONTROL-X CONTROL-F**

When you use CONTROL-X CONTROL-F, **emacs** partially completes the path to the filename you are to enter. Normally it is the path to the working directory, but in some situations **emacs** may display a different path, such as the path to your home directory. You can edit this path if it is not pointing to the directory you want.
Basic Editing Commands

This section takes a more detailed look at the fundamental emacs editing commands. It covers straightforward editing of a single file in a single window.

Keys: Notation and Use

Mainstream emacs uses the 128-character ASCII character set. ASCII keyboards have a typewriter-style SHIFT key and a CONTROL key. Some keyboards also have a META (diamond or ALT) key that controls the eighth bit. It takes seven bits to describe an ASCII character; the eighth bit of an eight-bit byte can be used to communicate other information. Because so much of the emacs command set is in the nonprinting CONTROL or META case, Stallman was one of the first to confront the problem of developing a notation for writing about keystrokes.

His solution, although not popular outside the emacs community, is clear and unambiguous (Table 7-1). It uses the capital letters C and M to denote holding down the CONTROL and META (or ALT) keys, respectively, and a few simple acronyms for the most common special characters, such as RET (this book uses RETURN), LFD (LINEFEED), DEL (DELETE), ESC (ESCAPE), SPC (SPACE), and TAB. Most emacs documentation, including the online help, uses this notation.

<table>
<thead>
<tr>
<th>Character</th>
<th>Classic emacs notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>(lowercase) a</td>
<td>a</td>
</tr>
<tr>
<td>(uppercase) SHIFT-a</td>
<td>A</td>
</tr>
<tr>
<td>CONTROL-a</td>
<td>C-a (do not use SHIFT), equivalent to CONTROL-a</td>
</tr>
<tr>
<td>CONTROL-A</td>
<td>M-a (do use SHIFT), different from M-a</td>
</tr>
<tr>
<td>META-a</td>
<td>M-a</td>
</tr>
<tr>
<td>META-A</td>
<td>M-A (do use SHIFT), different from M-a</td>
</tr>
<tr>
<td>CONTROL-META-a</td>
<td>C-M-a (not used frequently)</td>
</tr>
<tr>
<td>META-CONTROL-a</td>
<td></td>
</tr>
</tbody>
</table>

This use of keys had some problems. Many keyboards had no META key, and some operating systems discarded the META bit. In addition, the emacs character set clashes with XON-XOFF flow control, which also uses CONTROL-S and CONTROL-Q.

Although the flow-control problem still exists, the META key issue was resolved by making it an optional two-key sequence starting with ESCAPE. For instance, you can type ESCAPE-a instead of META-a or type ESCAPE CONTROL-A to get CONTROL-META-a . If the keyboard you are using does not have a META or ALT key, you can use the two-key ESCAPE sequence by pressing the ESCAPE key, releasing it, and then pressing the key following the META key in this book. For example, when this book says to press META-r, you can either press the META or ALT key while you press r or press and release ESCAPE and then press r.

tip: The notation used in this book

This book uses an uppercase letter following the CONTROL key and a lowercase letter following the META key. In either case you do not have to hold down the SHIFT key while entering a CONTROL or META character. Although the META uppercase character (that is, META-A) is a different character, it is usually set up to cause no action or the same effect as its lowercase counterpart.
**Key Sequences and Commands**

In *emacs* the relationship between key sequences (one or more keys that are pressed together or in sequence to issue an *emacs* command) and commands is very flexible, and there is considerable opportunity for exercising your personal preference. You can translate and remap key sequences to other commands and replace or reprogram commands.

Although most *emacs* documentation glosses over the details and talks about keystrokes as though they were the commands, it is important to recognize that the underlying machinery remains separate from the key sequences and to understand that you can change the behavior of the key sequences and the commands. For more information refer to "Customizing *emacs*" on page 235.

**META-x: Running a Command Without a Key Binding**

The *emacs* keymaps (the tables, or vectors, that *emacs* uses to translate key sequences to commands [page 237]) are very crowded, and often it is not possible to bind every command to a key sequence. You can execute any command by name by preceding it with META-x. When you press META-x, the *emacs* editor prompts you for a command in the Echo Area. After you enter the command name and press RETURN, it executes the command.

**Smart completion**

When a command has no common key sequence, it is sometimes described as META-x *command-name*. The *emacs* editor has a *smart completion* for most prompted answers, using SPACE or TAB to complete, if possible, to the end of the current word or the whole command, respectively. Forcing a completion past the last unambiguous point or typing ? displays a list of alternatives. You can find more details on smart completion in the online *emacs* manual.

**Numeric Arguments**

Some of the *emacs* editing commands accept a numeric argument as a repetition count. You place this argument immediately before the key sequence for the command. Absence of an argument almost always means a count of 1. Even an ordinary alphabetic character can have a numeric argument, which means "insert this many times." To give a command a numeric argument, you can do either of the following:

- Press META with each digit (0–9) or the minus sign (\(^{-}\)). For example, to insert 10 *z* characters, type META-1 META-0 *z*.
- Use CONTROL-U to begin a string of digits, including the minus sign. For example, to move the cursor forward 20 words, type CONTROL-U 20 META-f.

**CONTROL-U**

For convenience, CONTROL-U defaults to multiply by 4 when you do not follow it with a string of one or more digits. For example, entering CONTROL-U *r* means insert *rrrr* (4 * 1), whereas CONTROL-U CONTROL-U *r* means insert *rrrrrrrrrrrrrrrrrrrr* (4 * 4 * 1). For quick partial scrolling of a tall window, you may find it convenient to use repeated sequences of CONTROL-U CONTROL-V to scroll down four lines, CONTROL-U META-v to scroll up four lines, CONTROL-U CONTROL-U CONTROL-V to scroll down 16 lines, or CONTROL-U CONTROL-U META-v to scroll up 16 lines.
Point and the Cursor

Point is the place in a buffer where editing takes place and is where the cursor is positioned. Strictly speaking, Point is the left edge of the cursor; it is thought of as lying between two characters.

Each window has its own Point, but there is only one cursor. When the cursor is in a window, moving the cursor also moves Point. Switching the cursor out of a window does not change that window's Point; it is in the same place when you switch the cursor back to that window.

All of the cursor-movement commands described previously also move Point.

Scrolling Through a Buffer

CONTROL-V META-v
CONTROL-L

A buffer is likely to be much larger than the window through which it is viewed, so you need a way of moving the display of the buffer contents up or down to position the interesting part in the window. Scrolling forward refers to moving the text upward, with new lines entering at the bottom of the window. Use CONTROL-V or the PAGEDOWN key to scroll forward one window (minus two lines for context). Scrolling backward refers to moving the text downward, with new lines entering at the top of the window. Use META-v or the PAGEUP key to scroll backward one window (again leaving two lines for context). Pressing CONTROL-L clears the screen and repaints it, moving the current line to the center of the window. This command is useful if the screen becomes garbled.

A numeric argument to CONTROL-V or META-v means "scroll that many lines"; thus CONTROL-U 10 CONTROL-V means scroll forward ten lines. A numeric argument to CONTROL-L means "scroll the text so the cursor is on that line of the window," where 0 means the top line and 1 means the bottom, just above the Mode Line. Scrolling occurs automatically if you exceed the window limits with CONTROL-P or CONTROL-N.

META-<META->

You can move the cursor to the beginning of the buffer with META-< or to the end of the buffer with META->.

Erasing Text

Delete versus kill

When you erase text you can discard it or move it into a holding area and optionally bring it back later. The term delete means permanently discard, and the term kill means move to a holding area. The holding area, called the Kill Ring, can hold several pieces of killed text. You can use the text in the Kill Ring in many ways (refer to "Cut and Paste: Yanking Killed Text" on page 215).

The META-d command kills from the cursor forward to the end of the current word. CONTROL-K kills forward to the end of the current line. It does not delete the line-ending LINEFEED character unless Point and the cursor are just to the left of the LINEFEED. This setup allows you to reach the left end of a line with CONTROL-A, kill the whole line with CONTROL-K, and then immediately type a replacement line without having to reopen a hole for the new line. Another consequence is that, from the beginning of the line, it takes CONTROL-K CONTROL-K (or CONTROL-U 2 CONTROL-K) to kill the text and close the hole.
Searching

The *emacs* editor has several types of search commands. You can search in the following ways:

- Incrementally for a character string
- Incrementally for a regular expression (possible but uncommon)
- For a complete character string
- For a complete regular expression ([Appendix A](#))

You can run each of the four types of searches either forward or backward in the buffer.

The *complete* searches behave in the same manner as a search on other editors. Searching begins only when the search string is complete. In contrast, an *incremental* search begins when you type the first character of the search string and keeps going as you enter additional characters. Initially this approach may sound confusing, but it is surprisingly useful.

Incremental Searches

**CONTROL-S CONTROL-R**

A single command selects the direction of and starts an incremental search. CONTROL-S starts a forward incremental search, and CONTROL-R starts a reverse incremental search.

When you start an incremental search, *emacs* prompts you with **I-search**: in the Echo Area. When you enter a character, it immediately searches for that character in the buffer. If it finds that character, *emacs* moves Point and cursor to that position so you can see the search progress. If the search fails, *emacs* tells you so.

After you enter each character of the search string, you can take one of several actions depending on the result of the search to that point.

- The search finds the string you are looking for in the buffer, leaving the cursor positioned just to its right. Stop the search and leave the cursor in its new position by pressing RETURN. (Any *emacs* command not related to searching will also stop the search but remembering exactly which ones apply can be difficult. For a new user, RETURN is safer.)

- The search finds a string but it is not the one you are looking for. You can refine the search string by adding another letter, press CONTROL-R or CONTROL-S again to look for the next occurrence of this search string, or press RETURN to stop the search and leave the cursor where it is.

- The search hits the beginning or end of the buffer and reports **Failing I-Search**. You can proceed in several ways at this point.
  - If you mistyped the search string, press BACKSPACE as needed to remove characters from the search string. The text and cursor in the window jump backward in step with your removal of characters.
  - If you want to wrap past the beginning or end of the buffer and continue searching, you can force a wrap by pressing CONTROL-R or CONTROL-S again.
If the search has not found the string you are looking for but you want to leave the cursor at its current position, press RETURN to stop the search.

If the search has gone wrong and you just want to get back to where you started, press CONTROL-G (the quit character). From an unsuccessful search a single CONTROL-G backs out all the characters in the search string that could not be found. If this action returns you to a place you wish to continue searching from, you can add characters to the search string again. If you do not want to continue the search from that position, a second CONTROL-G stops the search and leaves the cursor where it was initially.

Nonincremental Searches

CONTROL-S RETURN CONTROL-R RETURN

If you prefer that your searches succeed or fail without showing all the intermediate results, you can give the nonincremental command CONTROL-S RETURN to search forward or CONTROL-R RETURN to search backward. Searching does not begin until you enter a search string in response to the emacs prompt and press RETURN again. Neither of these commands wraps past the end of the buffer.

Regular Expression Searches

You can perform both incremental and nonincremental regular expression searching in emacs. Use the commands listed in Table 7-2 to begin a regular expression search.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-CONTROL-s</td>
<td>Incrementally searches forward for a regular expression; prompts for a regular expression one character at a time</td>
</tr>
<tr>
<td>META-x isearch-backward-regexp</td>
<td>Incrementally searches backward for a regular expression; prompts for a regular expression one character at a time</td>
</tr>
<tr>
<td>META-x isearch-complete RETURN</td>
<td>Prompts for and then searches forward for a complete regular expression</td>
</tr>
<tr>
<td>META-x isearch-backward-regexp RETURN</td>
<td>Prompts for and then searches backward for a complete regular expression</td>
</tr>
</tbody>
</table>
Online Help

The **emacs** help system is always available. With the default key bindings, you can start it with CONTROL-H. The help system then prompts you for a one-letter help command. If you do not know which help command you want, type ? or CONTROL-H to switch the current window to a list of help commands, each with a one-line description; **emacs** again requests a one-letter help command. If you decide you do not want help after all, type CONTROL-G to cancel your help request and return to the former buffer.

If the help output is only a single line, it appears in the Echo Area. If it consists of more text, the output appears in its own window. Use CONTROL-V and META-v to scroll forward and backward through the buffer (page 206). You can move the cursor between windows with CONTROL-X o (lowercase "o"). See page 222 for a discussion on working with multiple windows.

On many terminals the BACKSPACE or LEFT ARROW key generates CONTROL-H. If you forget that you are using **emacs** and try to back over a few characters, you may unintentionally enter the help system. This action does not pose a danger to the buffer you are editing, but it can be unsettling to lose the window contents and not have a clear picture of how to restore it. While you are being prompted for the type of help you want you can type CONTROL-G to remove the prompt and return to editing the buffer. Some users elect to put help on a different key (page 237). Table 7-3 lists some of the help commands.

### Table 7-3. Help commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Type of help offered</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-H a</td>
<td>Prompts for a string and displays a list of commands whose names contain that string.</td>
</tr>
<tr>
<td>CONTROL-H b</td>
<td>Displays a long table of the key bindings in effect.</td>
</tr>
<tr>
<td>CONTROL- H c key-sequence</td>
<td>Displays the name of the command bound to key-sequence. Multiple key sequences are allowed. For a long key sequence where only the first part is recognized, the command describes the first part and quietly inserts the unrecognized part into the buffer. This can happen with three-character function keys (F1, F2, and so on, on the keyboard) that generate character sequences such as ESCAPE [ SHIFT.</td>
</tr>
<tr>
<td>CONTROL-H f</td>
<td>Prompts for the name of a Lisp function and displays the documentation for it. Because commands are Lisp functions, you can use a command name with this command.</td>
</tr>
<tr>
<td>CONTROL-H i</td>
<td>Displays the top info (page 32) menu where you can browse emacs or other documentation.</td>
</tr>
<tr>
<td>CONTROL-H k key-sequence</td>
<td>Displays the name and documentation of the command bound to key-sequence. (See the notes on CONTROL-H c.)</td>
</tr>
<tr>
<td>CONTROL-H l (lowercase &quot;l&quot;)</td>
<td>Displays the last 100 characters typed. The record is kept after the first-stage keyboard translation. If you have customized the keyboard translation table, you must make a mental reverse translation.</td>
</tr>
<tr>
<td>CONTROL-H m</td>
<td>Displays the documentation and special key bindings for the current Major mode (Text, C, Fundamental, and so on, [page 226]).</td>
</tr>
<tr>
<td>CONTROL-H n</td>
<td>Displays the emacs news file which lists recent changes to emacs, ordered with the most recent changes first. See the tip &quot;Closing the help window&quot; on page 210.</td>
</tr>
<tr>
<td>CONTROL-H t</td>
<td>Runs an emacs tutorial session. See the tip &quot;Closing the help window&quot; on page 210.</td>
</tr>
<tr>
<td>CONTROL-H v</td>
<td>Prompts for a Lisp variable name and displays the documentation for that variable.</td>
</tr>
<tr>
<td>CONTROL-H w</td>
<td>Prompts for a command name and identifies any key sequence bound to that</td>
</tr>
</tbody>
</table>
Command

Type of help offered

command. Multiple key sequences are allowed. (See the notes on CONTROL-H c.)

tip: Closing the help window

To delete the help window while the cursor is in the window that holds the text you are editing, type CONTROL-X 1 (one). Alternatively, you can move the cursor to the help window (CONTROL-X 0 [lowercase "o"]) and type CONTROL-X 0 (zero) to delete the current window.

If help displays a window that occupies the entire screen, as is the case with CONTROL-H n (emacs news) and CONTROL-H t (emacs tutorial), you can kill the help buffer with CONTROL-X k or use CONTROL-X b to switch buffers (both on page 220).

As this abridged presentation makes clear, you can use the help system to browse through the emacs internal Lisp system. For the curious, following is Stallman's list of strings that match many names in the Lisp system. To get a view of the internal functionality of emacs, you can use any of these strings with CONTROL-H a (help system list of commands) or META-x apropos (prompts for a string and lists variables whose names contain that string).

backward  dir   insert   previous  view
beginning  down   kill     region   what
buffer     end     line     register  window
case       file     list     screen   word
change     fill    mark     search   yank
char       find    mode     sentence
defun      forward  next     set
delete     goto    page     sexp
describe   indent   paragraph  up
Advanced Editing

The basic **emacs** commands suffice for many editing tasks but the serious user will quickly discover the need for more power. This section presents some of the more advanced **emacs** capabilities.

Undoing Changes

An editing session begins when you read a file into an **emacs** buffer. At that point the buffer content matches the file exactly. As you insert text and give editing commands, the buffer content becomes increasingly more different from the file. If you are satisfied with the changes, you can write the altered buffer back out to the file and end the session.

Near the left end of the Mode Line (Figure 7-1, page 198) is an indicator that shows the modification state of the buffer that is displayed in the window. The three possible states are ¬ (not modified), ** (modified), and % % (readonly).

The **emacs** editor keeps a record of all the keys you have pressed (text and commands) since the beginning of the editing session, up to a limit currently set at 20,000 characters. If you are within this limit, it is possible to undo the entire session for this buffer, one change at a time. If you have multiple buffers (page 220), each buffer has its own undo record.

Undoing is considered so important that it has a backup key sequence, just in case some keyboards cannot easily handle the primary sequence. The two sequences are CONTROL- (underscore, which on old ASR-33 TTY keyboards was LEFT ARROW) and CONTROL-X u. When you type CONTROL-, **emacs** undoes the last command and moves the cursor to that position in the buffer so you can see what happened. If you type CONTROL- a second time, the next-to-last command is undone, and so on. If you keep typing CONTROL- eventually you will get the buffer back to its original unmodified state and the ** Mode Line indicator will change to ¬ ¬.

When you break the string of Undo commands with *anything* (text or any command except Undo), all reverse changes you made during the string of undos become a part of the change record and can themselves be undone. This strategy offers a way to redo some or all the undo operations. If you decide you backed up too far, type a command (something innocuous, such as CONTROL-F , that does not change the buffer), and begin undoing in reverse. Table 7-4 lists some examples of Undo commands.

<table>
<thead>
<tr>
<th>Commands</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-</td>
<td>Undoes the last change</td>
</tr>
<tr>
<td>CONTROL- CONTROL-F CONTROL-</td>
<td>Undoes the last change and changes it back again</td>
</tr>
<tr>
<td>CONTROL- CONTROL-</td>
<td>Undoes the last two changes</td>
</tr>
<tr>
<td>CONTROL- CONTROL- CONTROL-F CONTROL-</td>
<td>Undoes two changes and changes them both back again</td>
</tr>
<tr>
<td>CONTROL- CONTROL- CONTROL-F CONTROL-</td>
<td>Undoes two changes and changes one of them back again</td>
</tr>
</tbody>
</table>

If you do not remember the last change you made, you can type CONTROL- and undo it. If you wanted to make this change, type CONTROL-F CONTROL- and make it again. If you modified a buffer by accident, you can keep typing CONTROL- until the Mode Line indicator shows ¬ ¬ once more.

If the buffer is completely ruined and you want to start over, issue the command META-x **revert-buffer** to discard
If the buffer is completely ruined and you want to start over, issue the command `META-x revert-buffer` to discard the current buffer contents and reread the associated file. The `emacs` editor asks you to confirm this command.

Mark and Region

Point is the current editing position in a buffer which you can move anywhere within the buffer by moving the cursor. It is also possible to set a marker called *Mark* in the buffer. The contiguous characters between Point and Mark (either one may come first) are called the *Region*. Many commands operate on a buffer's Region, not just on the characters near Point.

Moving Mark and Establishing a Region

`CONTROL-@ CONTROL-SPACE CONTROL-X CONTROL-X`

Mark is not as easy to move as Point. Once set, Mark can be moved only by setting it somewhere else. Each buffer has only one Mark. The `CONTROL-@` (or `CONTROL-SPACE`) command explicitly sets Mark at the current cursor (and Point) position. Some keyboards generate `CONTROL-@` when you type `CONTROL-Q`. Although this is not really a backup key binding, it is occasionally a convenient alternative. You can use `CONTROL-X CONTROL-X` to exchange Point and Mark (and move the cursor to the new Point).

To establish a Region, you usually position the cursor (and Point) at one end of the desired Region, set Mark with `CONTROL-@`, and then move the cursor (and Point) to the other end of the Region. If you forget where you left Mark, you can move the cursor back to it again with `CONTROL-X CONTROL-X` or hop back and forth with repeated `CONTROL-X CONTROL-X` to show the Region more clearly.

If a Region boundary is not to your liking, you can swap Point and Mark using `CONTROL-X CONTROL-X` to move the cursor from one end of the Region to the other and then move Point. Continue until you are satisfied with the Region.

Operating on a Region

*Table 7-5* lists selected commands that operate on a Region. Give the command `CONTROL-H a region` to see a complete list of these commands.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>META-w</code></td>
<td>Copies the Region nondestructively (without killing it) to the Kill Ring</td>
</tr>
<tr>
<td><code>CONTROL-W</code></td>
<td>Kills the Region</td>
</tr>
<tr>
<td><code>META-x print-region</code></td>
<td>Sends the Region to the printer</td>
</tr>
<tr>
<td><code>META-x append-to-buffer</code></td>
<td>Prompts for a buffer and appends the Region to that buffer</td>
</tr>
<tr>
<td><code>META-x append-to-file</code></td>
<td>Prompts for a filename and appends the Region to that file</td>
</tr>
<tr>
<td><code>META-x capitalize-region</code></td>
<td>Converts the Region to uppercase</td>
</tr>
</tbody>
</table>

The Mark Ring

Each time you set Mark in a buffer, you are also pushing Mark's former location onto the buffer's *Mark Ring*. The
Mark Ring is organized as a FIFO (first-in-first-out) list and holds the 16 most recent locations where Mark was set. Each buffer has its own Mark Ring. This record of recent Mark history is useful because it often holds locations that you want to jump back to quickly. Jumping to a location pointed to by the Mark Ring can be faster and easier than scrolling or searching your way through the buffer to find the site of a previous change.

**CONTROL-U CONTROL-@**

To work your way backward along the trail of former Mark locations, give the command CONTROL-U CONTROL-@ one or more times. Each time you give the command, **emacs**

- Moves Point (and the cursor) to the current Mark location
- Saves the current Mark location at the *oldest* end of the Mark Ring
- Pops off the *youngest* (most recent) Mark Ring entry and sets Mark

Each additional CONTROL-U CONTROL-@ command causes **emacs** to move Point and the cursor to the previous entry on the Mark Ring.

Although this process may seem complex, it really just makes a safe jump to a previous Mark location. It is safe because each jump's starting point is recirculated through the Mark Ring, where it is easy to find again. You can jump to all previous locations on the Mark Ring (it may be fewer than 16) by giving the command CONTROL-U CONTROL-@ again and again. You can go around the ring as many times as you like and stop whenever you want.

**Setting Mark Automatically**

Some commands set Mark automatically: The idea is to leave a bookmark before moving Point a long distance. For example, META-> sets Mark before jumping to the end of the buffer. You can then return to your starting position with CONTROL-U CONTROL-@. Searches behave similarly. To avoid surprises the message **Mark Set** appears in the Echo Area whenever Mark is set, either explicitly or implicitly.

**Cut and Paste: Yanking Killed Text**

Recall that killed text is not discarded but rather is kept in the Kill Ring. The Kill Ring holds the last 30 pieces of killed text and is visible from all buffers.

Retrieving text from the Kill Ring is called *yanking*. This terminology is the opposite of that used in **vim**: In **vim** *yanking* pulls text from the buffer, and *putting* puts text into the buffer. Killing and yanking—which are roughly analogous to cutting and pasting—are **emacs**’s primary mechanisms for moving and copying text. Table 7-6 lists the most common kill and yank commands.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-d</td>
<td>Kills to end of current word</td>
</tr>
<tr>
<td>META-D</td>
<td>Kills from beginning of previous word</td>
</tr>
<tr>
<td>CONTROL-K</td>
<td>Kills to end of line, not including LINEFEED</td>
</tr>
<tr>
<td>CONTROL-U 1</td>
<td>Kills to end of line, including LINEFEED</td>
</tr>
<tr>
<td>Command</td>
<td>Result</td>
</tr>
<tr>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>CONTROL-U 0 CONTROL-K</td>
<td>Kills from beginning of line</td>
</tr>
<tr>
<td>META-w</td>
<td>Copies the Region (between Point and Mark) to the Kill Ring but does not erase the Region from the buffer</td>
</tr>
<tr>
<td>CONTROL-W</td>
<td>Kills the Region (between Point and Mark)</td>
</tr>
<tr>
<td>META-z char</td>
<td>Kills up to next occurrence of char</td>
</tr>
<tr>
<td>CONTROL-Y</td>
<td>Yanks the most recently killed text into the current buffer at Point, sets Mark at the beginning of this text, and positions Point and the cursor at the end</td>
</tr>
<tr>
<td>META-y</td>
<td>Erases the just-yanked text, rotates the Kill Ring, and yanks the next item (only after CONTROL-Y or META-y)</td>
</tr>
</tbody>
</table>

To move two lines of text, move Point to the beginning of the first line and then enter CONTROL-U 2 CONTROL-K to kill two lines. Next move Point to the destination position, and enter CONTROL-Y.

To copy two lines of text, move Point to the beginning of the first line and give the commands CONTROL-U 2 CONTROL-K CONTROL-Y to kill and then yank back immediately. Then move Point to the destination position and type CONTROL-Y.

To copy a larger piece of the buffer, set the Region to cover this piece and then type CONTROL-W CONTROL-Y to kill and yank back at once. Next move Point to the destination, and type CONTROL-Y. You can also set the Region and use META-w to copy the Region to the Kill Ring.

The Kill Ring is organized as a fixed-length FIFO list, with each new entry causing the eldest to be discarded (once you build up to 30 entries). Simple cut-and-paste operations generally use only the newest entry. The older entries are retained to give you time to change your mind about a deletion. If you do change your mind you can "mine" the Kill Ring like an archaeological dig, working backward through time and down through the strata of killed material to copy a specific item back into the buffer.

To view every entry in the Kill Ring, begin a yanking session by pressing CONTROL-Y. This action copies the youngest entry to your buffer at the current cursor position. If this entry is not the item you want, continue the yanking session by pressing META-y. This action erases the previous yank and copies the next youngest entry to the buffer at the current cursor position. If this still is not the item you wanted, press META-y again to erase it and retrieve a copy of the next entry, and so on. You can continue giving META-y commands all the way back to the oldest entry. If you continue to press META-y, you wrap back to the youngest entry again. In this manner you can examine each entry as many times as you wish.

The sequence used in a yanking session consists of CONTROL-Y followed by any mixture of CONTROL-Y and META-y. If you type any other command after META-y, the sequence is broken and you must give the CONTROL-Y command again to start another yanking session.

As you work backward in the Kill Ring, it is useful to think of this process as advancing a Last Yank pointer back through history to increasingly older entries. This pointer is not reset to the youngest entry until you give a new kill command. Using this technique, you can work backward partway through the Kill Ring with CONTROL-Y and a few META-y commands, give some commands that do not kill, and then pick up where you left off with another CONTROL-Y and a succession of META-y commands.

It is also possible to position the Last Yank pointer with positive or negative numeric arguments to META-y. Refer to the online documentation for more information.

**Inserting Special Characters**

As stated earlier, `emacs` inserts everything that is not a command into the buffer at the position of the cursor. To
As stated earlier, emacs inserts everything that is not a command into the buffer at the position of the cursor. To insert characters that would ordinarily be emacs commands, you can use the emacs escape character: CONTROL-Q. There are two ways of using this escape character:

- CONTROL-Q followed by any other character inserts that character in the buffer, no matter what command interpretation it was supposed to have.
- CONTROL-Q followed by three octal digits inserts a byte with that value in the buffer.

**tip: CONTROL-Q**

Depending on the way your terminal is set up, CONTROL-Q may clash with software flow control. If CONTROL-Q seems to have no effect, it is most likely being used for flow control. In that case you must bind another key to the command quoted-insert (page 237).

**Global Buffer Commands**

The vim editor and its predecessors have global commands for bufferwide search and replace operations. Their default operating Region is the entire buffer. The emacs editor has a similar family of commands. Their operating Region begins at Point and extends to the end of the buffer. If you wish to operate on the entire buffer, use META-< to set Point at the beginning of the buffer before issuing the command.

**Line-Oriented Operations**

The commands listed in Table 7-7 take a regular expression and apply it to the lines between Point and the end of the buffer.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-x occur</td>
<td>Prompts for a regular expression and copies each line with a match for the expression in a buffer named <em>Occur</em></td>
</tr>
<tr>
<td>META-x delete-matching-lines</td>
<td>Prompts for a regular expression and deletes each line with a match for the expression</td>
</tr>
<tr>
<td>META-x delete-non-matching-lines</td>
<td>Prompts for a regular expression and deletes each line that does not have a match for that expression</td>
</tr>
</tbody>
</table>

The META-x **occur** command puts its output in a special buffer named *Occur*, which you can peruse and discard or use as a jump menu to reach each line quickly. To use the *Occur* buffer as a jump menu, switch to it (CONTROL-X o [lowercase "o"]), move the cursor to the copy of the desired destination line, and type CONTROL-C CONTROL-C. This command moves the cursor to the buffer that was searched and positions it on the line that the regular expression matched.

As with any buffer change, you can undo the deletion commands.

**Unconditional and Interactive Replacement**

The commands listed in Table 7-8 operate on the characters between Point and the end of the buffer, changing every string match or regular expression match. An unconditional replacement makes all replacements automatically. An
interactive replacement gives you the opportunity to see and approve each replacement before it is made.

<table>
<thead>
<tr>
<th>Table 7-8. Replacement commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command</td>
</tr>
<tr>
<td>META-x replace-string</td>
</tr>
<tr>
<td>META-x replace-regexp</td>
</tr>
<tr>
<td>META-% string or META-x query-replace</td>
</tr>
<tr>
<td>META-x query-replace-regexp</td>
</tr>
</tbody>
</table>

If you perform an interactive replacement, emacs displays each instance of string or match for regexp and prompts you for an action to take. Table 7-9 lists some of the possible responses.

<table>
<thead>
<tr>

</tr>
<tr>
<td>. (period)</td>
</tr>
<tr>
<td>! (exclamation point)</td>
</tr>
</tbody>
</table>

Files

When you visit (emacs terminology for "call up") a file, emacs reads it into a buffer (page 220), allows you to edit the buffer, and eventually saves the buffer back to the file. The commands discussed here relate to visiting and saving files.

META-x pwd META-x cd

Each emacs buffer keeps a record of its default directory (the directory the file was read from or the working directory, if it is a new file) that is prepended to any relative pathname you specify. This convenience is meant to
save some typing. Enter META-x `pwd` to print the default directory for the current buffer or META-x `cd` to prompt for a new default directory and assign it to this buffer.

**Visiting Files**

The `emacs` editor deals well with visiting a file that has already been called up and whose image is now in a buffer. After a check of the modification time to ensure that the file has not been changed since it was last called up, `emacs` simply switches to that buffer. Table 7-10 lists commands used to visit files.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-X CONTROL-F</td>
<td>Prompts for a filename and reads its contents into a freshly created buffer. Assigns the file's simple filename as the buffer name. Other buffers are unaffected. It is common and often useful to have several files open simultaneously for editing.</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-V</td>
<td>Prompts for a filename and replaces the current buffer with a buffer containing the contents of the requested file. The current buffer is destroyed.</td>
</tr>
<tr>
<td>CONTROL-X 4 CONTROL-F</td>
<td>Prompts for a filename and reads its contents into a new buffer. Assigns the file's simple filename as the buffer name. Creates a new window for this buffer and selects that window. The window selected before the command still displays the buffer it was showing before this operation, although the new window may cover up part of the old window.</td>
</tr>
</tbody>
</table>

To create a new file, simply call it up. An empty buffer is created and properly named so you can eventually save it. The message *(New File)* appears in the Echo Area, reflecting `emacs`'s understanding of the situation. Of course, if this "new file" grew out of a typographical error, you will probably want to issue CONTROL-X CONTROL-V with the correct name.

**Saving Files**

You save a buffer by copying its contents back to the original file you called up. The relevant commands are listed in Table 7-11.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-X CONTROL-S</td>
<td>This workhorse file-saving command saves the current buffer into its original file. If the current buffer is not modified, you get the following message: <em>(No changes need to be saved).</em></td>
</tr>
<tr>
<td>CONTROL-X s</td>
<td>For each modified buffer, you are asked whether you wish to save it. Answer y or n. This command is given automatically as you exit from <code>emacs</code> and allows you to save any buffers that have been modified but not yet written out. If you want to save intermediate copies of your work, you can give this command at any time.</td>
</tr>
<tr>
<td>META-x set-visited-file-name</td>
<td>Prompts for a filename and sets this name as the current buffer's &quot;original&quot; name.</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-W</td>
<td>Prompts for a filename, sets this name as the &quot;original&quot; name for the current buffer, and saves the current buffer into that file. It is equivalent to META-x <code>set-visited-</code></td>
</tr>
</tbody>
</table>
Command | Result
---|---
META-~ (tilde) | file-name followed by CONTROL-X CONTROL-S. Clears modified flag from the current buffer. If you mistakenly typed META-~ against a buffer with changes you want to keep, you need to make sure that the modified condition and its -- indicator are turned back on before leaving emacs, or all the changes will be lost. One easy way to do this is to insert a SPACE into the buffer and then remove it again with DELETE.
META-x rename-buffer | Prompts for a new buffer name and gives this new name to the current buffer.
CONTROL-X CONTROL-Q | Toggles the current buffer's readonly status and the associated %% Mode Line indicator. This can be useful to prevent accidental buffer modification or to allow modification of a buffer when visiting a readonly file.
META-x append-to-buffer | Prompts for a buffer name and appends the Region (between Point and Mark) to the end of that buffer.
META-x prepend-to-buffer | Prompts for a buffer name and prepends the Region (between Point and Mark) to the beginning of that buffer.
META-x copy-to-buffer | Prompts for a buffer name and deletes the contents of the buffer before copying the Region (between Point and Mark) to that buffer.
META-x insert-buffer | Prompts for a buffer name and inserts the entire contents of that buffer into the current buffer at Point.
CONTROL-X k | Prompts for a buffer name and deletes that buffer. If the buffer is modified but unsaved, you are asked to confirm the operation.
META-x kill-some-buffers | Goes through the entire buffer list and offers the chance to delete each buffer. As with CONTROL-X k, you are asked to confirm the kill command if a modified buffer is not yet saved.

caution: Did you modify a buffer by mistake?

Buffers

An emacs buffer is a storage object that you can edit. It often holds the contents of a file but can also exist without being associated with a file. You can select only one buffer at a time, designated as the current buffer. Most commands operate only on the current buffer, even when multiple windows show two or more buffers on the screen. For the most part each buffer is its own world: It has its own name, its own modes, its own file associations, its own modified state, and perhaps its own special key bindings. You can use the commands shown in Table 7-12 to create, select, list, and manipulate buffers.

Table 7-12. Work with buffers

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-X b</td>
<td>Prompts for a buffer name and selects it. If the buffer you name does not exist, this command creates it.</td>
</tr>
<tr>
<td>CONTROL-X 4 b</td>
<td>Prompts for a buffer name and selects it in another window. The existing window is not disturbed, although the new window may overlap it.</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-B</td>
<td>Create a buffer named * Buffer list * and displays it in another window. The existing window is not disturbed, although the new window may overlap it. The new buffer is not selected. In the * Buffer list * buffer, each buffer's data is shown along with the name, size, mode(s), and original filename. A % appears for a readonly buffer, a * indicates a modified buffer, and . appears for the selected buffer.</td>
</tr>
<tr>
<td>META-x rename-buffer</td>
<td>Prompts for a new buffer name and gives this new name to the current buffer.</td>

</tr>
<tr>
<td>CONTROL-X k</td>
<td>Prompts for a buffer name and deletes that buffer. If the buffer is modified but unsaved, you are asked to confirm the operation.</td>
</tr>
<tr>
<td>META-x kill-some-buffers</td>
<td>Goes through the entire buffer list and offers the chance to delete each buffer. As with CONTROL-X k, you are asked to confirm the kill command if a modified buffer is not yet saved.</td>
</tr>
</tbody>
</table>
When you give a CONTROL-X s command, you may discover files whose buffers were modified by mistake as emacs tries to save the wrong changes back to the file. When emacs prompts you to confirm the save, do not answer y if you are not sure. First exit from the CONTROL-X s dialog by typing n to any saves you are not sure about. You then have several options:

- Save the suspicious buffer into a temporary file with CONTROL-X CONTROL-W and analyze it later.
- Undo the changes with a string of CONTROL-_ commands until the ** indicator disappears from the buffer's Mode Line.
- If you are sure that all the changes are wrong, use META-x revert-buffer to get a fresh copy of the file.
- Kill the buffer outright. Because it is modified, emacs asks whether you are sure before carrying out this command.
- Give the META-~ (tilde) command to clear the modified condition and ** indicator. A subsequent CONTROL-X s then believes that the buffer does not need to be written.

caution: You can exit without first getting a warning

Clearing the modified flag (META-~) allows you to exit without saving a modified buffer with no warning. Make sure you know what you are doing when you use META-~.

Windows

An emacs window is a viewport that looks into a buffer. The emacs screen begins by displaying a single window, but this screen space can later be divided among two or more windows. On the screen the current window holds the cursor and views the current buffer. For a tip on terminology, see "The screen and emacs windows" on page 197.

A window views one buffer at a time. You can switch the buffer that a window views by giving the command CONTROL-X b buffer-name in the current window. Multiple windows can view one buffer; each window may view different parts of the same buffer; and each window has its own Point value. Any change to a buffer is reflected in all the windows viewing that buffer. Also, a buffer can exist without a window open on it.

Splitting a Window

One way to divide the screen is to split the starting window explicitly into two or more pieces. The command CONTROL-X 2 splits the current window in two, with one new window appearing above the other. A numeric argument is taken as the size of the upper window in lines. The command CONTROL-X 3 splits the current window in two, with the new windows being arranged side by side (Figure 7-7). A numeric argument is taken as the number of columns to give the left window. For example, CONTROL-U CONTROL-X 2 splits the current window in two; because of the special "times 4" interpretation of CONTROL-U standing alone, the upper window is given four lines (barely enough to be useful).

Figure 7-7. Splitting a window vertically
Although these commands split the current window, both windows continue to view the same buffer. You can select a new buffer in either or both new windows, or you can scroll each window to show different portions of the same buffer.

Manipulating Windows

**CONTROL-X o META-CONTROL-V**

You can use CONTROL-X o (lowercase "o") to select the other window. If more than two windows appear on the screen, a sequence of CONTROL-X o commands cycles through them in top-to-bottom, left-to-right order. The META-CONTROL-V command scrolls the other window. If more than two windows are visible, the command scrolls the window that CONTROL-X o would select next. You can use a positive or negative scrolling argument, just as with CONTROL-V scrolling in the current window.

Other-Window Display

**CONTROL-X 4b CONTROL-X 4f**

In normal emacs operation, explicit window splitting is not nearly as common as the implicit splitting done by the family of CONTROL-X 4 commands. The CONTROL-X 4b command, for example, prompts for a buffer name and selects it in the other window. If there is no other window, this command begins with a half-and-half split that arranges the windows one above the other. The CONTROL-X 4f command prompts for a filename, calls it up in the other window, and selects the other window. If there is no other window, this command begins with a half-and-half split that arranges the windows one above the other.
Adjusting and Deleting Windows

CONTROL-X 0 CONTROL-X 1

Windows may be destroyed when they get in the way. No data is lost in the window’s associated buffer with this operation, and you can make another window whenever you like. The CONTROL-X 0 (zero) command deletes the current window and gives its space to its neighbors; CONTROL-X 1 deletes all windows except the current window.

META-x shrink-window CONTROL-X ^ CONTROL-X } CONTROL-X {

You can also adjust the dimensions of the current window, once again at the expense of its neighbors. To make a window shorter, use META-x shrink-window. Use CONTROL-X ^ to increase the height of a window, CONTROL-X } to make the window wider, and CONTROL-X { to make the window narrower. Each of these commands adds or subtracts one line or column to or from the window, unless you precede the command with a numeric argument.

The emacs editor has its own guidelines for a window’s minimum useful size and may destroy a window before you force one of its dimensions to zero. Although the window may disappear, the buffer remains intact.

Foreground Shell Commands

The emacs editor can run a subshell (a shell that is a child of the shell that is running emacs) to execute a single command line, optionally with standard input coming from the Region of the current buffer and optionally with standard output replacing the Region (Table 7-13). This process is analogous to executing a shell command from the vim editor and having the input come from the file you are editing and the output go back to the same file (page 183). As with vim, how well this process works depends in part on the capabilities of the shell.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-! (exclamation point)</td>
<td>Prompts for a shell command, executes it, and displays the output</td>
</tr>
<tr>
<td>CONTROL-U META-! (exclamation point)</td>
<td>Prompts for a shell command, executes it, and inserts the output at Point</td>
</tr>
<tr>
<td>META-</td>
<td>(vertical bar)</td>
</tr>
<tr>
<td>CONTROL-U META-</td>
<td>(vertical bar)</td>
</tr>
</tbody>
</table>

The emacs editor can also start an interactive subshell that runs continuously in its own buffer. See "Shell Mode" on page 234 for more information.

Background Shell Commands

The emacs editor can run processes in the background, with their output being fed into a growing emacs buffer that does not have to remain in view. You can continue editing while the background process runs and look at its
output later. Any shell command can be run in this way.

The growing output buffer is always named *compilation*. You can read it, copy from it, or edit it in any way, without waiting for the background process to finish. Most commonly this buffer is used to review the output of program compilation and to correct any syntax errors found by the compiler.

META-x compile

To run a process in the background, give the command META-x compile to prompt for a shell command and begin executing it as a background process. The screen splits in half to show the *compilation* buffer.

You can switch to the *compilation* buffer and watch the execution, if you wish. To make the display scroll as you watch, position the cursor at the very end of the text with a META-> command. If you are not interested in this display just remove the window with CONTROL-X 0 (zero) if you are in it or CONTROL-X 1 otherwise and keep working. You can switch back to the *compilation* buffer later with CONTROL-X b.

You can kill the background process with META-x kill-compilation. The emacs editor asks for confirmation and then kills the background process.

If standard format error messages appear in *compilation*, you can automatically visit the line in the file where each error occurred. Give the command CONTROL-X ' (back tick) to split the screen into two windows and visit the file and line of the next error message. Scroll the *compilation* buffer until this error message appears at the top of its window. Use CONTROL-U CONTROL-X ' to start over with the first error message and visit that file and line.
Language-Sensitive Editing

The *emacs* editor has a large collection of feature sets, each specific to a certain variety of text. The feature sets are called Major modes. A buffer can have only one Major mode at any time.

A buffer's Major mode is private to the buffer and does not affect editing in any other buffer. If you switch to a new buffer having a different mode, rules for the new mode immediately take effect. To avoid confusion, the name of a buffer's Major mode appears in the Mode Line of any window viewing that buffer (Figure 7-1 on page 198).

The three classes of Major modes are used for the following tasks:

- Editing human languages (for example, text, *nroff*, TeX)
- Editing programming languages (for example, C, Fortran, Lisp)
- Special purposes (for example, shell, mail, dired, *ftp*)

In addition, one Major mode—Fundamental—does nothing special. A Major mode usually sets up the following:

- Special commands unique to the mode, possibly with their own key bindings. Languages may have just a few special commands, but special-purpose modes may have dozens.

- Mode-specific character syntax and regular expressions defining word constituent characters, delimiters, comments, whitespace, and so on. This setup conditions the behavior of commands oriented to syntactic units, such as words, sentences, comments, or parenthesized expressions.

Selecting a Major Mode

**META-x modename**

The *emacs* editor chooses and sets a mode when a file is called up by matching the filename against a set of regular expression patterns describing the filename and filename extension. The explicit command to enter a Major mode is META-x *modename*. This command is rarely used except to correct wrong guesses.

A file can define its own mode by including the text \*modename\* somewhere in the first nonblank line, possibly inside a comment suitable for that programming language.

Human-Language Modes

A *human* language is meant eventually to be used by humans, possibly after being formatted by some text-formatting program. Human languages share many conventions about the structure of words, sentences, and paragraphs. With regard to these textual units, the major human language modes all behave in the same way.

Beyond this area of commonality, each mode offers additional functionality oriented to a specific text formatter, such as TeX, *LaTeX*, or *nroff*. Text-formatter extensions are beyond the scope of this presentation; the focus here is on the commands relating to human textual units (for example, words, sentences, and paragraphs).

Words

As a mnemonic aid, the bindings for words are defined parallel to the character-oriented bindings CONTROL-F,
CONTROL-B, CONTROL-D, DELETE, and CONTROL-T.

Just as CONTROL-F and CONTROL-B move forward and backward over characters, META-f and META-b move forward and backward over words. They may start from a position inside or outside the word to be traversed, but in all cases Point finishes just beyond the word, adjacent to the last character skipped over. Both commands accept a numeric argument specifying the number of words to be traversed.

Just as CONTROL-D and DELETE delete characters forward and backward, the keys META-d and META-DELETE kill words forward and backward. They leave Point in exactly the same finishing position as META-f and META-b do, but they kill the words they pass over. They also accept a numeric argument.

META-t transposes the word before Point with the word after Point.

Sentences

As a mnemonic aid, three of the bindings for sentences are defined parallel to the line-oriented bindings: CONTROL-A, CONTROL-E, and CONTROL-K. The META-a command moves backward to the beginning of a sentence, and META-e moves forward to the end of a sentence. In addition, CONTROL-X DELETE kills backward to the beginning of a sentence; META-k kills forward to the end of a sentence.

The emacs editor recognizes the ends of sentences by referring to a regular expression that is kept in a variable named sentence-end. (If you are curious, give the command CONTROL-H v sentence-end RETURN to view this variable.) Briefly, it looks for the characters ., ?, or ! followed by two SPACEs or an end-of-line marker, possibly with close quotation marks or close braces.

The META-a and META-e commands leave Point adjacent to the first or last nonblank character in the sentence. They accept a numeric argument specifying the number of sentences to traverse; a negative argument runs them in reverse.

The META-k and CONTROL-X DELETE commands kill sentences forward and backward, in a manner analogous to CONTROL-K line kill. They leave Point in exactly the same finishing position as META-a and META-e do, but they kill the sentences they pass over. They also accept a numeric argument. CONTROL-X DELETE is useful for quickly backing out of a half-finished sentence.

Paragraphs

The META-{ command moves backward to the most recent paragraph beginning, and META-} moves forward to the next paragraph ending. The META-h command marks the paragraph (that is, puts Point at the beginning and Mark at the end) that the cursor is currently on, or the next paragraph if it is between paragraphs.

The META-) and META-{ commands leave Point at the beginning of a line, adjacent to the first character or last character of the paragraph. They accept a numeric argument specifying the number of paragraphs to traverse and run in reverse if given a negative argument.

In human-language modes, paragraphs are separated by blank lines and text-formatter command lines, and an indented line starts a paragraph. Recognition is based on the regular expressions stored in the variables paragraph-separate and paragraph-start. A paragraph is composed of complete lines, including the final line terminator. If a paragraph starts following one or more blank lines, the last blank line before the paragraph belongs to the paragraph.
The emacs editor can fill a paragraph to fit a specified width, breaking lines and rearranging them as necessary. Breaking takes place only between words and no hyphenation occurs. Filling can be done automatically as you type or in response to an explicit command.

The META-x auto-fill-mode command toggles Auto Fill mode on and off. When Auto Fill mode is on, emacs automatically breaks lines when you press SPACE or RETURN and are currently beyond the specified line width. This feature is useful when you are entering new text.

Auto Fill mode does not automatically refill the entire paragraph you are currently working on. If you add new text in the middle of a paragraph, Auto Fill mode breaks your new text as you type but does not refill the complete paragraph. To refill a complete paragraph or Region of paragraphs, use either META-q to refill the current paragraph or META-x fill-region to refill each paragraph in the Region between Point and Mark.

You can change the filling width from its default value of 70 by setting the fill-column variable. Use CONTROL-X f to set fill-column to the current cursor position and CONTROL-U nnn CONTROL-X f to set fill-column to nnn, where 0 is the left margin.

Case Conversion

The emacs editor can force words or Regions to all uppercase, all lowercase, or initial caps (the first letter of each word uppercase, the rest lowercase). Refer to Table 7-14.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META- l (lowercase &quot;l&quot;)</td>
<td>Converts word to the right of Point to lowercase</td>
</tr>
<tr>
<td>META-u</td>
<td>Converts word to the right of Point to uppercase</td>
</tr>
<tr>
<td>META-c</td>
<td>Converts word to the right of Point to initial caps</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-L</td>
<td>Converts the Region (between Point and Mark) to lowercase</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-U</td>
<td>Converts the Region (between Point and Mark) to uppercase</td>
</tr>
</tbody>
</table>

The word-oriented conversions move Point over the word just converted (just as META-f does), allowing you to walk through text and convert each word with META-l, META-u, or META-c, or skip over words to be left alone with META-f. A positive numeric argument converts that number of words to the right of Point, moving Point as it goes. A negative numeric argument converts that number of words to the left of Point but leaves Point stationary. This feature is useful for quickly changing the case of words you have just typed. Table 7-15 shows some examples.

<table>
<thead>
<tr>
<th>Characters and commands</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>HELLO</td>
<td>META- l (lowercase &quot;l&quot;) hello</td>
</tr>
<tr>
<td>hello</td>
<td>META-u HELLO</td>
</tr>
<tr>
<td>hello</td>
<td>META-c Hello</td>
</tr>
</tbody>
</table>

The word conversions are not picky about beginning in the middle of a word. In all cases, they consider the first word-constituent character to the right of Point as the beginning of the word to be converted.
Text Mode

With very few exceptions, the commands for human-language text units, such as words and sentences, are always turned on and available, even in the programming-language modes. Text mode adds very little to these basic commands but is still worth turning on just to get the TAB key. Use the command META-x text-mode to activate Text mode.

In Text mode TAB runs the function tab-to-tab-stop. By default TAB stops are set every eight columns. You can adjust them with META-x edit-tab-stops, which switches to a special *Tab Stops* buffer. The current stops are laid out in this buffer on a scale for you to edit. The new stops are installed when or if you type CONTROL-C CONTROL-C. Of course, you are free to kill this buffer (CONTROL-X k) or switch away from it (CONTROL-X b) without ever changing the stops.

The tab stops you set with the META-x edit-tab-stops command affect only the interpretation of TAB characters arriving from the keyboard. The emacs editor automatically inserts enough spaces to reach the TAB stop. This command does not affect the interpretation of TAB characters already in the buffer or the underlying file. If you edit the TAB stops and then use them, you can still print the file and the hard copy will look the same as the text on the screen.

C Mode

Programming languages are read by humans but are interpreted by machines. Besides continuing to handle some of the human-language text units (for example, words and sentences), the major programming-language modes address several additional problems:

- **Balanced expressions** enclosed by parentheses, brackets, or braces as textual units
- Comments as textual units
- Indention

The emacs editor includes Major modes to support C, Fortran, and several variants of Lisp. In addition, many users have contributed modes for their favorite languages. In these modes the commands for human textual units are still available, with occasional redefinitions. For example, a paragraph is bounded only by blank lines and indentation does not signal a paragraph start. In addition, each mode has custom coding to handle the language-specific conventions for balanced expressions, comments, and indentation. This presentation discusses only C mode.

Expressions

The emacs Major modes are limited to lexical analysis. They can recognize most tokens (for example, symbols, strings, and numbers) and all matched sets of parentheses, brackets, and braces. This is enough for Lisp but not for C. The C mode lacks a full-function syntax analyzer and is not prepared to recognize all of C's possible expressions. [1]

[1] In the emacs documentation the recurring term sexp refers to the Lisp term S-expression. Unfortunately, it is sometimes used interchangeably with expression, even though the language might not be Lisp.

Table 7-16 lists the emacs commands applicable to parenthesized expressions and some tokens. By design the bindings run parallel to the CONTROL commands for characters and the META commands for words. All these commands accept a numeric argument and run in reverse if that argument is negative.
Table 7-16. Commands for expressions and tokens

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-META-f</td>
<td>Moves forward over an expression. The exact behavior depends on which character lies to the right of Point (or left of Point, depending on which direction you are moving Point).</td>
</tr>
<tr>
<td></td>
<td>• If the first nonwhitespace is an opening delimiter (parenthesis, bracket, or brace), Point is moved just past the matching closing delimiter.</td>
</tr>
<tr>
<td></td>
<td>• If the first nonwhitespace is a token, Point is moved just past the end of this token.</td>
</tr>
<tr>
<td>CONTROL-META-b</td>
<td>Moves backward over an expression.</td>
</tr>
<tr>
<td>CONTROL-META-k</td>
<td>Kills an expression forward. This command leaves Point at the same finishing position as CONTROL-META-f but kills the expression it traverses.</td>
</tr>
<tr>
<td>CONTROL-META-@</td>
<td>Sets Mark at the position CONTROL-META-f would move to but does not change Point. To see the marked Region clearly, give a pair of CONTROL-X CONTROL-X commands to interchange Point and Mark.</td>
</tr>
</tbody>
</table>
The emacs C mode has extensive logic to control the indentation of C programs. Furthermore, you can adjust this logic for many different styles of C indentation (Table 7-18).

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>TAB</td>
<td>Adjusts the indentation of the current line. TAB inserts or deletes whitespace at the beginning of the line until the indentation conforms to the current context and rules in effect. Point is not moved unless it lies in the whitespace area; in that case it is moved to the end of the whitespace. TAB does not insert anything except leading whitespace, so you can hit it at any time and at any position in the line. If you really want to insert a tab in the text, use META-i or CONTROL-Q TAB.</td>
</tr>
<tr>
<td>LINEFEED</td>
<td>Shorthand for RETURN followed by TAB. The LINEFEED key is a convenience for entering new code, giving you an autoindent as you begin each line.</td>
</tr>
</tbody>
</table>

The next two commands indent multiple lines with a single command.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-META-q</td>
<td>Reindents all lines inside the next pair of matched braces. CONTROL-META-q assumes that the left brace is correctly indented and drives the indentation from there. If you need to adjust the left brace type TAB just to the left of the brace before giving this command. All lines up to the matching brace are indented as if you had typed TAB on each one.</td>
</tr>
<tr>
<td>CONTROL-META-\</td>
<td>Reindents all lines in the Region (between Point and Mark). Put Point just to the left of a left brace and then give the command. All lines up to the matching brace are indented as if you had typed TAB on each one.</td>
</tr>
</tbody>
</table>

Customizing Indention

Many styles of C programming have evolved, and emacs does its best to support automatic indentation for all of them. The indentation coding was completely rewritten for emacs version 19; it supports C, C++, Objective-C, and Java. The new emacs syntactic analysis is much more precise and can classify each syntactic element of each line of program text into a single syntactic category (out of about 50), such as statement, string, or else-clause. With the result of that analysis in hand, emacs goes to an offset table named c-offsets-alist and looks up how much each line should be indented from the preceding line.

To customize indentation, you must change the offset table. It is possible to define a completely new offset table for each customized style but much more convenient to feed in a short list of exceptions to the standard rules. Each mainstream style (GNU, K&R [Kernighan and Ritchie], BSD, and so on) has such an exception list; all are collected in c-style-alist. Here is one entry from c-style-alist:

"gnu"

(c-basic-offset . 2)
(c-comment-only-line-offset . (0 . 0))
(c-offsets-alist . ((statement-block-intro . +)
                 (knr-argdecl-intro . 5))
Constructing a custom style is beyond the scope of this book. If you are curious, the long story is available in emacs online info beginning at “Customizing C Indentation.” The sample .emacs file given in this chapter (page 239) adds a very simple custom style and arranges to use it on every .c file that is edited.

Comments

Each buffer has its own comment-column variable, which you can view with the CONTROL-H v comment-column RETURN help command. Table 7-19 lists commands that facilitate working with comments.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-;</td>
<td>Inserts a comment on the current line or aligns an existing comment. This command's behavior differs according to the situation.</td>
</tr>
<tr>
<td></td>
<td>• If no comment is on this line, META-; creates an empty comment at the value of comment-column.</td>
</tr>
<tr>
<td></td>
<td>• If text already on this line overlaps the position of comment-column, META-; creates an empty comment one SPACE after the end of the text.</td>
</tr>
<tr>
<td></td>
<td>• If a comment is already on this line but not at the current value of comment-column, META-; realigns the comment at that column. If text is in the way, it places the comment one SPACE after the end of the text.</td>
</tr>
<tr>
<td>CONTROL-X ;</td>
<td>Sets comment-column to the column after Point. The left margin is column 0.</td>
</tr>
<tr>
<td>CONTROL-U CONTROL-X ;</td>
<td>Kills the comment on the current line. This command sets comment-column from the first comment found above this line and then performs a META-; command to insert or align a comment at that position.</td>
</tr>
<tr>
<td>CONTROL-U CONTROL-X ;</td>
<td>Sets comment-column to the position of the first comment found above this line and then executes a META-; command to insert or align a comment on this line.</td>
</tr>
</tbody>
</table>
Special-Purpose Modes

The **emacs** editor includes a third family of Major modes that are not oriented toward a particular language or even toward ordinary editing. Instead, these modes perform some special function. The following modes may define their own key bindings and commands to accomplish that function:

- **Rmail**: reads, archives, and composes email
- **Dired**: moves around in an `ls -l` display and operates on files
- **VIP**: simulates a complete `vi` environment
- **VC**: allows you to drive version-control systems (including RCS, CVS, and Subversion) from within **emacs**
- **GUD**: Grand Unified Debugger; allows you to run and debug C (and other) programs from within **emacs**
- **Tramp**: allows you to edit files on any remote system you can reach with `ftp` or `scp`
- **Shell**: runs an interactive subshell from inside an **emacs** buffer

This book discusses only Shell mode.

Shell Mode

One-time shell commands and Region filtering were discussed earlier; refer to "Foreground Shell Commands" on page 224. In Shell mode, however, each **emacs** buffer has an underlying interactive shell permanently associated with it. This shell takes its input from the last line of the buffer and sends its output back to the buffer, advancing Point as it goes. If you do not edit the buffer, it holds a record of the complete shell session.

The shell runs asynchronously, whether or not you have its buffer in view. The **emacs** editor uses idle time to read the shell's output and add it to the buffer.

Type `META-x shell` to create a buffer named `*shell*` and start a subshell. If a buffer named `*shell*` already exists, **emacs** just switches to that buffer. The shell that this command runs is taken from one of the following sources:

- The Lisp variable `explicit-shell-file-name`
- The environment variable `ESHELL`
- The environment variable `SHELL`

To start a second shell, first use `META-x rename-buffer` to change the name of the existing shell's buffer, and then use `META-x shell` to start another shell. You can create as many subshells and buffers as you like, all running in parallel.

A special set of commands is defined in Shell mode (Table 7-20). They are bound mostly to two-key sequences starting with CONTROL-C. Each sequence is similar to the ordinary control characters found in Linux but uses a leading CONTROL-C.
Table 7-20. Shell mode

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>RETURN</td>
<td>If Point is at the end of the buffer, <strong>emacs</strong> inserts the RETURN and sends this (the last) line to the shell. If Point is elsewhere, it copies this line to the end of the buffer, peeling off the old shell prompt (see the regular expression <strong>shell-prompt-pattern</strong>), if one existed. Then this copied line is now the last in the buffer and is sent to the shell.</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-D</td>
<td>Sends CONTROL-D to the shell or its subshell.</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-C</td>
<td>Sends CONTROL-C to the shell or its subshell.</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-\</td>
<td>Sends a quit signal to the shell or its subshell.</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-U</td>
<td>Kills the text on the current line not yet completed.</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-R</td>
<td>Scrolls back to the beginning of the last shell output, putting the first line of output at the top of the window.</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-O</td>
<td>Deletes the last batch of shell output.</td>
</tr>
</tbody>
</table>
optional: Customizing emacs

At the heart of emacs is a Lisp interpreter written in C. This version of Lisp is significantly extended with many special commands specifically oriented to editing. The interpreter's main task is to execute the Lisp-coded system that implements the look-and-feel of emacs.

Reduced to its essentials, this system implements a continuous loop that watches keystrokes arrive, parses them into commands, executes those commands, and updates the screen. This behavior can be customized in a number of ways.

- As single keystrokes come in, they are mapped immediately through a keyboard translation table. By changing the entries in this table, it is possible to swap keys. If you are used to vi or vim, you can swap DELETE and CONTROL-H. Then CONTROL-H backspaces as it does in vim, and DELETE (which is not used by vim) is the help key. If you use DELETE as an interrupt key, you may want to choose another key to swap with CONTROL-H.

- The mapped keystrokes are gathered into small groups called key sequences. A key sequence may be only a single key, such as CONTROL-N, or may include two or more keys, such as CONTROL-X CONTROL-F. Once gathered the key sequences are used to select a particular procedure to be executed. The rules for gathering each key sequence and the specific procedure name to be executed when that sequence comes in are codified in a series of tables called keymaps. By altering the keymaps, you can change the gathering rules or change which procedure is associated with which sequence. If you are used to vi's or vim's use of CONTROL-W to back up over the word you are entering, you may want to change emacs's CONTROL-W binding from the standard kill-region to delete-word-backward.

- The command behavior is often conditioned by one or more global variables or options. It may be possible to get the behavior you want by setting some of these variables.

- The command itself is usually a Lisp program that can be reprogrammed to make it behave as desired. Although this task is not appropriate for beginners, the Lisp source to nearly all commands is available and the internal Lisp system is fully documented. As mentioned earlier, it is common practice to load customized Lisp code at startup time, even if you did not write it yourself.

Most emacs documentation glosses over all the translation, gathering, and procedure selection and talks about keystrokes as though they were commands. However, it is still important to know that the underlying machinery exists and to understand that its behavior can be changed.

THE .emacs STARTUP FILE

Each time you start emacs, it loads the file of Lisp code named ~/.emacs. Using this file is the most common way to customize emacs. Two command line options control the use of the .emacs file. The q option ignores the .emacs file so that emacs starts up without it; this is one way to get past a bad .emacs file. The u user option uses the ~ user/.emacs file (the .emacs file from the home directory of user).

The .emacs startup file is generally concerned only with key bindings and option settings; it is possible to write the Lisp statements for this file in a straightforward style. Each parenthesized Lisp statement is a Lisp function call. Inside the parentheses the first symbol is the function name; the rest of the SPACE-separated tokens are arguments to that function. The most common function in the .emacs file,setq, is a simple assignment to a global variable. The first argument is the name of the variable to set
and the second argument is its value. The following example sets the variable named \texttt{c-indent-level} to 8:

\begin{verbatim}
(setq c-indent-level 8)
\end{verbatim}

You can set the default value for a variable that is buffer-private by using the function name \texttt{setq-default}. To set a specific element of a vector, use the function name \texttt{aset}. The first argument is the name of the vector, the second is the target offset, and the third is the value of the target entry. In the startup file the new values are usually constants. \textbf{Table 7-21} shows the formats of these constants.

\begin{table}[h]
\centering
\caption{Formats of constants in \texttt{.emacs}}
\begin{tabular}{|l|l|}
\hline
\textbf{Command} & \textbf{Result} \\
\hline
Numbers & Decimal integers, with an optional minus sign \\
Strings & Similar to C strings but with extensions for CONTROL and META characters: \texttt{\textbackslash C-s} yields CONTROL-S, \texttt{\textbackslash M-s} yields META-s, and \texttt{\textbackslash M-C-s} yields CONTROL-META-s \\
Characters & \textit{Not} like C characters; start with ? and continue with a printing character or with a backslash escape sequence (for example, \texttt{?a}, \texttt{?\textbackslash C-i}, \texttt{?\textbackslash 033}) \\
Booleans & \textit{Not} 1 and 0; use \texttt{t} for \textit{true} and \texttt{nil} for \textit{false} \\
Other Lisp objects & Begin with a single quotation mark and continue with the object's name \\
\hline
\end{tabular}
\end{table}

\textbf{REMAPPING KEYS}

The \texttt{emacs} command loop begins each cycle by translating incoming keystrokes into the name of the command to be executed. The basic translation operation uses the ASCII value of the incoming character to index a 128-element vector called a \textit{keymap}.

Sometimes a character's eighth bit is interpreted as the META case, but this cannot always be relied on. At the point of translation all META characters appear with the ESCAPE prefix, whether or not they were actually typed that way.

Each position in this vector is one of the following:

- Not defined at all: No translation possible in this map.
- The name of another keymap: Switches to that keymap and waits for the next character to arrive.
- The name of a Lisp function to be called: Translation process is done; call this command.

Because keymaps can reference other keymaps, an arbitrarily complex recognition tree can be set up. The mainstream \texttt{emacs} bindings use at most three keys, with a very small group of well-known prefix keys, each with its well-known keymap name.

Each buffer can have a \textit{local keymap} that is used first for any keystrokes arriving while a window into that buffer is selected. The local keymap allows the regular mapping to be extended or overridden on a
that buffer is selected. The local keymap allows the regular mapping to be extended or overridden on a per-buffer basis and is most often used to add bindings for a Major mode.

The basic translation flow runs as follows:

- Map the first character through the buffer's local keymap. If it is defined as a Lisp function name, translation is done and `emacs` executes that function. If it is not defined, use this same character to index the global top-level keymap.

- Map the first character through the top-level global keymap `global-map`. At this and each following stage, the following conditions hold:
  - If the entry for this character is not defined, it is an error. Send a bell to the terminal and discard all the characters entered in this key sequence.
  - If the entry for this character is defined as a Lisp function name, translation is done and the function is executed.
  - If the entry for this character is defined as the name of another keymap, switch to that keymap and wait for another character to select one of its elements.

Everything must be a command or an error. Ordinary characters that are to be inserted in the buffer are usually bound to the command `self-insert-command`. Each of the well-known prefix characters is each associated with a keymap (Table 7-22).

### Table 7-22. Keymap prefixes

<table>
<thead>
<tr>
<th>Keymap prefix</th>
<th>Applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctl-x-map</td>
<td>For characters following CONTROL-X</td>
</tr>
<tr>
<td>ctl-x-4-map</td>
<td>For characters following CONTROL-X 4</td>
</tr>
<tr>
<td>esc-map</td>
<td>For characters following ESCAPE (including META characters)</td>
</tr>
<tr>
<td>help-map</td>
<td>For characters following CONTROL-H</td>
</tr>
<tr>
<td>mode-specific-map</td>
<td>For characters following CONTROL-C</td>
</tr>
</tbody>
</table>

To see the current state of the keymaps, type CONTROL-H `b`. They appear in the following order: local, global, and shorter maps for each prefix key. Each line specifies the name of the Lisp function to be called; the documentation for that function can be retrieved with the commands CONTROL-H `f function-name` or CONTROL-H `k key-sequence`.

The most common type of keymap customization is making small changes to the global command assignments without creating any new keymaps or commands. This type of customization is most easily done in the `.emacs` file using the Lisp function `define-key`. The `define-key` function takes three arguments:

- The keymap name
- A single character defining a position in that map
- The command to be executed when this character appears

For instance, to bind the command `backward-kill-word` to CONTROL-W, use the statement...
(define-key global-map "\C-w" 'backward-kill-word)

To bind the command kill-region to CONTROL-X CONTROL-K, use the statement

(define-key ctl-x-map "\C-k" 'kill-region)

The \ character causes C-w to be interpreted as CONTROL-W instead of three letters (equivalent to \^w). The unmatched single quotation mark in front of the command name is correct. This Lisp escape character keeps the name from being evaluated too soon.

A SAMPLE .emacs FILE

The following ~/.emacs file produces a plain editing environment that minimizes surprises for vi and vim users. Of course, if any section or any line is inapplicable or not to your liking, you can edit it out or comment it with one or more ; comment characters, beginning in column 1.

;;; Preference Variables

(setq make-backup-files nil) ; Do not make backup files
(setq backup-by-copying t) ; If you do, at least do not destroy links
(setq delete-auto-save-files t) ; Delete autosave files when writing orig
(setq blink-matching-paren nil) ; Do not blink opening delim
(setq-default case-fold-search nil) ; Do not fold cases in search
(setq require-final-newline 'ask) ; Ask about missing final newline

;;; Reverse mappings for C-h and DEL.
(keyboard-translate ?\C-h ?\177)
(keyboard-translate ?\177 ?\C-h)

;; reassigning C-w to keep on deleting words backward

;; C-w is supposed to be kill-region, but it's a great burden for
vi-trained fingers.

;; Bind it instead to backward-kill-word for more familiar,
friendly behavior.

(define-key global-map "\^w" 'backward-kill-word)

;; for kill-region use a two-key sequence c-x c-k.

(define-key ctl-x-map "\^k" 'kill-region)

;; C mode customization: set vanilla (8-space bsd) indentation style

(require 'cc-mode) ;kiss: be sure it's here

(c-add-style ;add indentation style
"bsd8" ;old bsd (8 spaces)
'((c-basic-offset . 8)
  (c-hanging-comment-ender-p . nil) ;isolated "*/" ends blk
  comments
  (c-comment-only-line-offset . 0)
  (c-offsets-alist . ((statement-block-intro . +)
    (knr-argdecl-intro . +)
    (substatement-open . 0)
(label . 0)

(statement-cont . +)

))

))

(add-hook ;this is our default style,
'c-mode-hook ;set it always in
  c-mode-hook
(function
  (lambda ()
    (c-set-style "bsd8"))))

;; end of c mode style setup
More Information

A lot of emacs documentation is available in both paper and electronic form. The GNU emacs Web page is a good place to start: www.gnu.org/software/emacs.

The comp.emacs and gnu.emacs.help newsgroups offer support for and a general discussion about emacs.

Access to emacs

The emacs editor is included with most Linux distributions. You can download and install emacs with Apt (page 850) or yum (page 848). You can download the latest version of the source code from www.gnu.org.

The Free Software Foundation can be reached at these addresses:

Mail: Free Software Foundation, Inc.

59 Temple Place, Suite 330

Boston, MA 02111-1307, USA

E-mail: gnu@gnu.org

Phone: 1 617-542-5942
**Chapter Summary**

You can precede many of the commands in the following tables with a numeric argument to make the command repeat the number of times specified by the argument. Precede a numeric argument with CONTROL-U to keep emacs from entering the argument as text.

Table 7-23 lists commands that move the cursor.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-F</td>
<td>Forward by characters</td>
</tr>
<tr>
<td>CONTROL-B</td>
<td>Backward by characters</td>
</tr>
<tr>
<td>META-f</td>
<td>Forward by words</td>
</tr>
<tr>
<td>META-b</td>
<td>Backward by words</td>
</tr>
<tr>
<td>META-e</td>
<td>To end of sentence</td>
</tr>
<tr>
<td>META-a</td>
<td>To beginning of sentence</td>
</tr>
<tr>
<td>META-}</td>
<td>To end of paragraph</td>
</tr>
<tr>
<td>META-{</td>
<td>To beginning of paragraph</td>
</tr>
<tr>
<td>META-&gt;</td>
<td>Forward to end of buffer</td>
</tr>
<tr>
<td>META-&lt;</td>
<td>Backward to beginning of buffer</td>

<td>Forward (down) one line</td>
</tr>
<tr>
<td>CONTROL-P</td>
<td>Backward (up) one line</td>
</tr>
<tr>
<td>CONTROL-V</td>
<td>Scroll forward (down) one window</td>
</tr>
<tr>
<td>META-v</td>
<td>Scroll backward (up) one window</td>
</tr>
<tr>
<td>CONTROL-L</td>
<td>Clear and repaint screen, and scroll current line to center of window</td>
</tr>
<tr>
<td>META-r</td>
<td>To beginning of middle line</td>
</tr>
</tbody>
</table>

Table 7-24 lists commands that kill and delete text.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-DELETE</td>
<td>Deletes character under cursor</td>
</tr>
<tr>
<td>DELETE</td>
<td>Deletes character to left of cursor</td>
</tr>
<tr>
<td>META-d</td>
<td>Kills forward to end of current word</td>
</tr>
<tr>
<td>META-DELETE</td>
<td>Kills backward to beginning of previous word</td>
</tr>
<tr>
<td>META-k</td>
<td>Kills forward to end of sentence</td>
</tr>
<tr>
<td>CONTROL-X DELETE</td>
<td>Kills backward to beginning of sentence</td>
</tr>
<tr>
<td>CONTROL-K</td>
<td>Kills forward, but not including, line-ending LINEFEED; if there is no text between the cursor and the LINEFEED, kills the LINEFEED</td>
</tr>
<tr>
<td>CONTROL-U 1 CONTROL-K</td>
<td>Kills from cursor forward to and including LINEFEED</td>
</tr>
<tr>
<td>CONTROL-U 0 CONTROL-K</td>
<td>Kills from cursor backward to beginning of line</td>

</tbody>
</table>
Table 7-25 lists commands that search for strings and regular expressions.

### Table 7-25. Search commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-z <strong>char</strong></td>
<td>Kills forward to, but not including, next occurrence of <strong>char</strong></td>
</tr>
<tr>
<td>META-w</td>
<td>Copies Region to Kill Ring (does not delete Region from buffer)</td>
</tr>
<tr>
<td>CONTROL-W</td>
<td>Kills Region (deletes Region from buffer)</td>
</tr>
<tr>
<td>CONTROL-Y</td>
<td>Yanks most recently killed text into current buffer at Point; sets Mark at beginning of this text, with Point and cursor at the end</td>
</tr>
<tr>
<td>META-y</td>
<td>Erases just-yanked text, rotates Kill Ring, and yanks next item (only after CONTROL-Y or META-y)</td>
</tr>
</tbody>
</table>

Table 7-26 lists commands that provide online help.

### Table 7-26. Online help

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-H a</td>
<td>Prompts for <strong>string</strong> and displays a list of commands whose names contain <strong>string</strong></td>
</tr>
<tr>
<td>CONTROL-H b</td>
<td>Displays a (long) table of all key bindings now in effect</td>
</tr>
<tr>
<td>CONTROL-H c <strong>key-sequence</strong></td>
<td>Displays the name of the command bound to <strong>key-sequence</strong></td>
</tr>
<tr>
<td>CONTROL-H k <strong>key-sequence</strong></td>
<td>Displays the name of and documentation for the command bound to <strong>key-sequence</strong></td>
</tr>
<tr>
<td>CONTROL-H f</td>
<td>Prompts for the name of a Lisp function and displays the documentation for that function</td>
</tr>
<tr>
<td>CONTROL-H i (lowercase &quot;i&quot;)</td>
<td>Displays the top menu of <strong>info</strong> (page 32)</td>
</tr>
<tr>
<td>CONTROL-H l (lowercase &quot;l&quot;)</td>
<td>Displays the last 100 characters typed</td>
</tr>
<tr>
<td>CONTROL-H m</td>
<td>Displays the documentation and special key bindings for the current Major mode</td>
</tr>
<tr>
<td>CONTROL-H n</td>
<td>Displays the <strong>emacs</strong> news file</td>
</tr>
<tr>
<td>CONTROL-H t</td>
<td>Starts an <strong>emacs</strong> tutorial session</td>
</tr>
<tr>
<td>CONTROL-H v</td>
<td>Prompts for a Lisp variable name and displays the documentation for that variable</td>
</tr>
<tr>
<td>CONTROL-H w</td>
<td>Prompts for a command name and displays the key sequence, if any, bound to that command</td>
</tr>
</tbody>
</table>

Table 7-27 lists commands that work with a Region.
### Table 7-27. Working with a Region

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-W</td>
<td>Copies Region nondestructively to the Kill Ring</td>
</tr>
<tr>
<td>CONTROL-W</td>
<td>Kills (deletes) Region</td>
</tr>
<tr>
<td>META-x print-region</td>
<td>Copies Region to the print spooler</td>
</tr>
<tr>
<td>META-x append-to-buffer</td>
<td>Prompts for buffer name and appends Region to that buffer</td>
</tr>
<tr>
<td>META-x append-to-file</td>
<td>Prompts for filename and appends Region to that file</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-U</td>
<td>Converts Region to uppercase</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-L</td>
<td>Converts Region to lowercase</td>
</tr>
</tbody>
</table>

Table 7-28 lists commands that work with lines.

### Table 7-28. Working with lines

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-x occur</td>
<td>Prompts for a regular expression and lists each line containing a match for the expression in a buffer named <em>Occur</em></td>
</tr>
<tr>
<td>META-x delete-matching-lines</td>
<td>Prompts for a regular expression and deletes lines from Point forward that have a match for the regular expression</td>
</tr>
<tr>
<td>META-x delete-non-matching-lines</td>
<td>Prompts for a regular expression and deletes lines from Point forward that do <em>not</em> have a match for the regular expression</td>
</tr>
</tbody>
</table>

Table 7-29 lists commands that replace strings and regular expressions unconditionally and interactively.

### Table 7-29. Commands that replace text

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-x replace-string</td>
<td>Prompts for two strings and replaces each instance of the first string with the second string from Mark forward; sets Mark at the start of the command</td>
</tr>
<tr>
<td>META-% or META-x query-replace</td>
<td>As above but queries for each replacement (see Table 7-30 for a list of responses)</td>
</tr>
<tr>
<td>META-x replace-regexp</td>
<td>Prompts for a regular expression and a string, and replaces each match for the regular expression with the string; sets Mark at the start of the command</td>
</tr>
<tr>
<td>META-x query-replace-regexp</td>
<td>As above but queries for each replacement (see Table 7-30 for a list of responses)</td>
</tr>
</tbody>
</table>

### Table 7-30. Responses to replacement queries

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>RETURN</td>
<td>Quits searching (does not make or query for any more replacements)</td>
</tr>
<tr>
<td>SPACE</td>
<td>Makes this replacement and continues querying</td>
</tr>
<tr>
<td>DELETE</td>
<td><em>Does not</em> make this replacement and continues querying</td>
</tr>
<tr>
<td>, (comma)</td>
<td>Makes this replacement, displays the result, and asks for another command</td>
</tr>
<tr>
<td>. (period)</td>
<td>Makes this replacement and does not make or query for any more replacements</td>
</tr>
<tr>
<td>! (exclamation point)</td>
<td>Replaces this and all remaining instances without querying</td>
</tr>
</tbody>
</table>
Table 7-30 lists responses to replacement queries.

Table 7-31 lists commands that work with windows.

### Table 7-31. Working with windows

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-X b</td>
<td>Prompts for and displays a different buffer in current window</td>
</tr>
<tr>
<td>CONTROL-X 2</td>
<td>Splits current window vertically into two</td>
</tr>
<tr>
<td>CONTROL-X 3</td>
<td>Splits current window horizontally into two</td>
</tr>
<tr>
<td>CONTROL-X o</td>
<td>Selects other window</td>
</tr>
<tr>
<td>META-CONTROL-V</td>
<td>Scrolls other window</td>
</tr>
<tr>
<td>CONTROL-X 4b</td>
<td>Prompts for buffer name and selects it in other window</td>
</tr>
<tr>
<td>CONTROL-X 4f</td>
<td>Prompts for filename and selects it in other window</td>
</tr>
<tr>
<td>CONTROL-X 0</td>
<td>Deletes current window</td>
</tr>
<tr>
<td>CONTROL-X 1</td>
<td>Deletes all windows except current window</td>
</tr>
<tr>
<td>META-x shrink-window</td>
<td>Makes current window one line shorter</td>
</tr>
<tr>
<td>CONTROL-X ^</td>
<td>Makes current window one line taller</td>
</tr>
<tr>
<td>CONTROL-X {</td>
<td>Makes current window one character wider</td>
</tr>
<tr>
<td>CONTROL-X }</td>
<td>Makes current window one character narrower</td>
</tr>
</tbody>
</table>

Table 7-32 lists commands that work with files.

### Table 7-32. Working with files

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-X CONTROL-F</td>
<td>Prompts for a filename and reads its contents into a new buffer; assigns the file's simple filename as the buffer name.</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-V</td>
<td>Prompts for a filename and reads its contents into the current buffer (overwriting the contents of the current buffer).</td>
</tr>
<tr>
<td>CONTROL-X 4 CONTROL-F</td>
<td>Prompts for a filename and reads its contents into a new buffer; assigns the file's simple filename as the buffer name. Creates a new window for the new buffer and selects that window. This command splits the screen in half if you begin with only one window.</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-S</td>
<td>Saves the current buffer to the original file.</td>
</tr>
<tr>
<td>CONTROL-X S</td>
<td>Prompts for whether to save each modified buffer (y/n).</td>
</tr>
<tr>
<td>META-x set-visited-file-name</td>
<td>Prompts for a filename and sets the current buffer's &quot;original&quot; name to that filename.</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-W</td>
<td>Prompts for a filename, sets the current buffer's &quot;original&quot; name to that filename, and saves the current buffer in that file.</td>
</tr>
<tr>
<td>META-~ (tilde)</td>
<td>Clears modified flag from the current buffer. Use with caution.</td>
</tr>
</tbody>
</table>

Table 7-33 lists commands that work with buffers.
<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-X CONTROL-S</td>
<td>Saves current buffer in its associated file.</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-F</td>
<td>Prompts for filename and visits (opens) that file.</td>
</tr>
<tr>
<td>CONTROL-X b</td>
<td>Prompts for buffer name and selects it. If that buffer does not exist, creates it.</td>
</tr>
<tr>
<td>CONTROL-X 4b</td>
<td>Prompts for buffer name and displays that buffer in another window. The existing window is not disturbed, although the new window may overlap it.</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-B</td>
<td>Creates a buffer named <em>Buffer List</em> and displays it in another window. The existing window is not disturbed, although the new window may overlap it. The new buffer is not selected. In the <em>Buffer List</em> buffer, each buffer's data is displayed with its name, size, mode(s), and original filename.</td>
</tr>
<tr>
<td>META-x rename-buffer</td>
<td>Prompts for a new buffer name and assigns this new name to the current buffer.</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-Q</td>
<td>Toggles the current buffer's readonly status and the associated %% Mode Line indicator.</td>
</tr>
<tr>
<td>META-x append-to-buffer</td>
<td>Prompts for buffer name and appends Region to the end of that buffer.</td>
</tr>
<tr>
<td>META-x prepend-to-buffer</td>
<td>Prompts for buffer name and prepends Region to beginning of that buffer.</td>
</tr>
<tr>
<td>META-x copy-to-buffer</td>
<td>Prompts for buffer name, deletes contents of that buffer, and copies the Region to that buffer.</td>
</tr>
<tr>
<td>META-x insert-buffer</td>
<td>Prompts for buffer name and inserts entire contents of that buffer in current buffer at Point.</td>
</tr>
<tr>
<td>CONTROL-X k</td>
<td>Prompts for buffer name and deletes that buffer.</td>
</tr>
<tr>
<td>META-x kill-some-buffers</td>
<td>Goes through the entire buffer list and offers the chance to delete each buffer.</td>
</tr>
</tbody>
</table>

Table 7-34 lists commands that run shell commands in the foreground. These commands may not work with all shells.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-! (exclamation point)</td>
<td>Prompts for shell command, executes it, and displays the output</td>
</tr>
<tr>
<td>CONTROL-U META-! (exclamation point)</td>
<td>Prompts for shell command, executes it, and inserts the output at Point</td>
</tr>
<tr>
<td>META-</td>
<td>(vertical bar)</td>
</tr>
<tr>
<td>CONTROL-U META-</td>
<td>(vertical bar)</td>
</tr>
</tbody>
</table>

Table 7-35 lists commands that run shell commands in the background.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-x compile</td>
<td>Prompts for shell command and runs that command in the background, with output going to the buffer named <em>compilation</em></td>
</tr>
<tr>
<td>META-x kill-compilation</td>
<td>Kills background process</td>
</tr>
</tbody>
</table>

Table 7-36 lists commands that convert text from uppercase to lowercase and vice versa.
### Table 7-36. Case conversion commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>META-l (lowercase &quot;l&quot;)</td>
<td>Converts word to right of Point to lowercase</td>
</tr>
<tr>
<td>META-u</td>
<td>Converts word to right of Point to uppercase</td>
</tr>
<tr>
<td>META-c</td>
<td>Converts word to right of Point to initial caps</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-L</td>
<td>Converts Region to lowercase</td>
</tr>
<tr>
<td>CONTROL-X CONTROL-U</td>
<td>Converts Region to uppercase</td>
</tr>
</tbody>
</table>

Table 7-37 lists commands that work in C mode.

### Table 7-37. C mode commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROL-META-f</td>
<td>Moves forward over expression</td>
</tr>
<tr>
<td>CONTROL-META-b</td>
<td>Moves backward over expression</td>
</tr>
<tr>
<td>CONTROL-META-k</td>
<td>Moves forward over expression and kills it</td>
</tr>
<tr>
<td>CONTROL-META-@</td>
<td>Sets Mark at the position CONTROL-META-f would move to, without changing Point</td>
</tr>
<tr>
<td>CONTROL-META-a</td>
<td>Moves to beginning of the most recent function definition</td>
</tr>
<tr>
<td>CONTROL-META-e</td>
<td>Moves to the end of the next function definition</td>
</tr>
<tr>
<td>CONTROL-META-h</td>
<td>Moves Point to beginning and Mark to end of current (or next, if between) function definition</td>
</tr>
</tbody>
</table>

Type META-x **shell** to create a buffer named *shell* and start a subshell. Table 7-38 lists commands that work on this buffer.

### Table 7-38. Shell mode commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>RETURN</td>
<td>Sends current line to the shell</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-D</td>
<td>Sends CONTROL-D to shell or its subshell</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-C</td>
<td>Sends CONTROL-C to shell or its subshell</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-\</td>
<td>Sends quit signal to shell or its subshell</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-U</td>
<td>Kills text on the current line not yet completed</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-R</td>
<td>Scrolls back to beginning of last shell output, putting first line of output at the top of the window</td>
</tr>
<tr>
<td>CONTROL-C CONTROL-O (uppercase &quot;O&quot;)</td>
<td>Deletes last batch of shell output</td>
</tr>
</tbody>
</table>
Exercises

1. Given a buffer full of English text, answer the following questions:

   a. How would you change every instance of his to hers?
   b. How would you do this only in the final paragraph?
   c. Is there a way to look at every usage in context before changing it?
   d. How would you deal with the possibility that His might begin a sentence?

2. Which command moves the cursor to the end of the current paragraph? Can you use this command to skip through the buffer in one-paragraph steps?

3. Suppose that you get lost in the middle of typing a long sentence.
   a. Is there an easy way to kill the botched sentence and start over?
   b. What if only one word is incorrect? Is there an alternative to backspacing one letter at a time?

4. After you have been working on a paragraph for a while, most likely some lines will have become too short and others too long. Is there a command to "neaten up" the paragraph without rebreaking all the lines by hand?

5. Is there a way to change the entire contents of the buffer to capital letters? Can you think of a way to change just one paragraph?

6. How would you reverse the order of two paragraphs?

7. How would you reverse two words?

8. Imagine that you saw a Usenet posting with something particularly funny in it and saved the posting to a file. How would you incorporate this file into your own buffer? What if you wanted only a couple of paragraphs? How would you add > to the beginning of each included line?

9. On the keyboard alone emacs has always offered a full set of editing possibilities. Generally several techniques will accomplish the same goal for any editing task. In the X environment the choice is enlarged still further with a new group of mouse-oriented visual alternatives. From these options you must select the way that you like to solve a given editing puzzle best.

   Consider this Shakespearean fragment:

   1. Full fathom five thy father lies;
   2. Of his bones are coral made;
3. Those are pearls that were his eyes:
4. Nothing of him that doth fade,
5. But doth suffer a sea-change
6. Into something rich and strange.
7. Sea-nymphs hourly ring his knell:
8. Ding-dong.
9. Hark! now I hear them--
10. Ding-dong, bell!

The following fragment has been typed with some errors:

1. Full fathiom five tyy father lies;
2. These are pearls that were his eyes:
3. Of his bones are coral made;
4. Nothin of him that doth fade,
5. But doth susffer a sea-change
6. Into something rich and strange.
7. Sea-nymphs hourly ring his knell:
8. Ding=dong.
9. Hard! now I hear them--
10. Ding-dong, bell!

Use only the keyboard to answer the following:

a. How many ways can you think of to move the cursor to the spelling errors?

b. Once the cursor is on or near the errors, how many ways can you think of to fix them?

c. Are there ways to fix errors without explicitly navigating to/searching for them? How
c. Are there ways to fix errors without explicitly navigating to/searching for them? How many can you think of?

d. Lines 2 and 3 are transposed. How many ways can you think of to correct this situation?
Advanced Exercises

10. Assume that your buffer contains the C code shown here, with the Major mode set for C and
the cursor positioned at the end of the while line as shown by the black square:

    /*
    * Copy string s2 to s1.  s1 must be large enough
    * return s1
    */
    char *
    strcpy(s1, s2)
    register char *s1, *s2;
    {
        register char *os1;

        os1 = s1;
        while (*s1++ = *s2++)
            ;
        return(os1);
    }

    /* Copy source into dest, stopping after '\0' is copied, and
      return a pointer to the '\0' at the end of dest.  Then our
caller
      can concatenate to the dest string with out another strlen
      call. */
    char *
    stpcpy (dest, source)
        char *dest;
char *source;
{
    while ((*dest++ = *source++) != '\0') /* void loop body */
    return (dest - 1);
}

a. Which command moves the cursor to the opening brace of `strcpy`? Which command moves the cursor past the closing brace? Can you use these commands to skip through the buffer in one-procedure steps?

b. Assume the cursor is just past the closing parenthesis of the `while` condition. How do you move to the matching opening parenthesis? How do you move back to the matching close parenthesis again? Does the same command set work for matched `[]` and `{}`? How does this differ from the `vim` `%` command?

c. One procedure is indented in the Berkeley indentation style; the other is indented in the GNU style. Which command reindents a line in accordance with the current indentation style you have set up? How would you reindent an entire procedure?

d. Suppose that you want to write five string procedures and intend to use `strcpy` as a starting point for further editing. How would you make five copies of the `strcpy` procedure?

e. How would you compile the code without leaving `emacs`?
Part III: THE SHELLS

CHAPTER 8 THE BOURNE AGAIN SHELL
CHAPTER 9 THE TC SHELL
Chapter 8. The Bourne Again Shell

IN THIS CHAPTER

Startup Files 257
Redirecting Standard Error 260
Writing a Simple Shell Script 263
Job Control 271
Manipulating the Directory Stack 274
Parameters and Variables 277
Processes 292
History 295
Reexecuting and Editing Commands 297
Aliases 312
Functions 315
Controlling bash Features and Options 318
Processing the Command Line 322

This chapter picks up where Chapter 5 left off by focusing on the Bourne Again Shell (bash). It notes where tcsh implementation of a feature differs from that of bash; if appropriate, you are directed to the page where the alternative implementation is discussed. Chapter 11 expands on this chapter, exploring control flow commands and more advanced aspects of programming the Bourne Again Shell. The bash home page is www.gnu.org/software/bash. The bash info page is a complete Bourne Again Shell reference.

The Bourne Again Shell and TC Shell (tcsh) are command interpreters and high-level programming languages. As command interpreters, they process commands you enter on the command line in response to a prompt. When you use the shell as a programming language, it processes commands stored in files called shell scripts. Like other languages, shells have variables and control flow commands (for example, for loops and if statements).

When you use a shell as a command interpreter, you can customize the environment you work in. You can make your prompt display the name of the working directory, create a function or alias for cp that keeps it from overwriting certain kinds of files, take advantage of keyword variables to change aspects of how the shell works, and so on. You can also write shell scripts that do your bidding, from a one-line script that stores a long, complex command to a longer script that runs a set of reports, prints them, and mails you a reminder when the job is done. More complex shell scripts are themselves programs; they do not just run other programs. Chapter 11 has some examples of these types of scripts.

Most system shell scripts are written to run under the Bourne Again Shell. If you will ever work in single-user mode—as when you boot your system or do system maintenance, administration, or repair work, for example—it is a good idea to become familiar with this shell.
This chapter expands on the interactive features of the shell described in Chapter 5, explains how to create and run simple shell scripts, discusses job control, introduces the basic aspects of shell programming, talks about history and aliases, and describes command line expansion. Chapter 9 covers interactive use of the TC Shell and TC Shell programming, and Chapter 11 presents some more challenging shell programming problems.
Background

The Bourne Again Shell is based on the Bourne Shell (the early UNIX shell; this book refers to it as the original Bourne Shell to avoid confusion), which was written by Steve Bourne of AT&T's Bell Laboratories. Over the years the original Bourne Shell has been expanded but it remains the basic shell provided with many commercial versions of UNIX.

sh Shell

Because of its long and successful history, the original Bourne Shell has been used to write many of the shell scripts that help manage UNIX systems. Some of these scripts appear in Linux as Bourne Again Shell scripts. Although the Bourne Again Shell includes many extensions and features not found in the original Bourne Shell, bash maintains compatibility with the original Bourne Shell so you can run Bourne Shell scripts under bash. On UNIX systems the original Bourne Shell is named sh. On Linux systems sh is a symbolic link to bash ensuring that scripts that require the presence of the Bourne Shell still run. When called as sh, bash does its best to emulate the original Bourne Shell.

Korn Shell

System V UNIX introduced the Korn Shell (ksh), written by David Korn. This shell extended many features of the original Bourne Shell and added many new features. Some features of the Bourne Again Shell, such as command aliases and command line editing, are based on similar features from the Korn Shell.

POSIX standards

The POSIX (the Portable Operating System Interface) family of related standards is being developed by PASC (IEEE's Portable Application Standards Committee, www.pasc.org). A comprehensive FAQ on POSIX, including many links, appears at www.opengroup.org/austin/papers/posix_faq.html.

POSIX standard 1003.2 describes shell functionality. The Bourne Again Shell provides the features that match the requirements of this POSIX standard. Efforts are under way to make the Bourne Again Shell fully comply with the POSIX standard. In the meantime, if you invoke bash with the -p option, the behavior of the Bourne Again Shell will more closely match the POSIX requirements.
Shell Basics

This section covers writing and using startup files, redirecting standard error, writing and executing simple shell scripts, separating and grouping commands, implementing job control, and manipulating the directory stack.

Startup Files

When a shell starts, it runs startup files to initialize itself. Which files the shell runs depends on whether it is a login shell, an interactive shell that is not a login shell (such as you get by giving the command `bash`), or a noninteractive shell (one used to execute a shell script). You must have read access to a startup file to execute the commands in it. Typically Linux distributions put appropriate commands in some of these files. This section covers `bash` startup files. See page 342 for information on `tcsh` startup files.

Login Shells

The files covered in this section are executed by login shells and shells that you start with the `-l` option. Login shells are, by their nature, interactive.

`/etc/profile`

The shell first executes the commands in `/etc/profile`. Superuser can set up this file to establish systemwide default characteristics for `bash` users.

`.bash_profile .bash_login .profile`

Next the shell looks for `~/.bash_profile`, `~/.bash_login`, and `~/.profile` (~ is shorthand for your home directory), in that order, executing the commands in the first of these files it finds. You can put commands in one of these files to override the defaults set in `/etc/profile`.

`.bash_logout`

When you log out, `bash` executes commands in the `~/.bash_logout` file. Frequently commands that clean up after a session, such as those that remove temporary files, go in this file.

Interactive Nonlogin Shells

The commands in the preceding startup files are not executed by interactive, nonlogin shells. However, these shells inherit from the login shell variables that are set by these startup files.

`/etc/bashrc`

Although not called by `bash` directly, many `~/.bashrc` files call `/etc/bashrc`. This setup allows Superuser to establish systemwide default characteristics for nonlogin `bash` shells.
.bashrc

An interactive nonlogin shell executes commands in the ~/.bashrc file. Typically a startup file for a login shell, such as .bash_profile, runs this file, so that both login and nonlogin shells benefit from the commands in .bashrc.

Noninteractive Shells

The commands in the previously described startup files are not executed by noninteractive shells, such as those that runs shell scripts. However, these shells inherit from the login shell variables that are set by these startup files.

BASH_ENV

Noninteractive shells look for the environment variable BASH_ENV (or ENV, if the shell is called as sh) and execute commands in the file named by this variable.

Setting Up Startup Files

Although many startup files and types of shells exist, usually all you need are the .bash_profile and .bashrc files in your home directory. Commands similar to the following in .bash_profile run commands from .bashrc for login shells (when .bashrc exists). With this setup, the commands in .bashrc are executed by login and nonlogin shells.

if [ -f ~/.bashrc ]; then source ~/.bashrc; fi

The [ -f ~/.bashrc ] tests whether the file named .bashrc in your home directory exists. See page 794 for more information on test and its synonym [ ].

**tip:** Use .bash_profile to set PATH

Because commands in .bashrc may be executed many times, and because subshells inherit exported variables, it is a good idea to put commands that add to existing variables in the .bash_profile file. For example, the following command adds the bin subdirectory of the home directory to PATH (page 284) and should go in .bash_profile:

PATH=$PATH:$HOME/bin

When you put this command in .bash_profile and not in .bashrc, the string is added to the PATH variable only once, when you log in.

Modifying a variable in .bash_profile allows changes you make in an interactive session to propagate to subshells. In contrast, modifying a variable in .bashrc overrides changes inherited from a parent shell.

Sample .bash_profile and .bashrc files follow. Some of the commands used in these files are not covered until later in this chapter. In any startup file, you must export variables and functions that you want to be available to child processes. For more information refer to "Locality of Variables" on page 475.
$ cat ~/.bash_profile

if [ -f ~/.bashrc ]; then
    source ~/.bashrc  # read local startup file if it exists
fi

PATH=$PATH:.  # add the working directory to PATH
export PS1='[\h \W \!]$ '  # set prompt

The first command in the preceding .bash_profile file executes the commands in the user's .bashrc file if it exists. The next command adds to the PATH variable (page 284). Typically PATH is set and exported in /etc/profile so it does not need to be exported in a user's startup file. The final command sets and exports PS1 (page 286), which controls the user's prompt.

Next is a sample .bashrc file. The first command executes the commands in the /etc/bashrc file if it exists. Next the LANG (page 290) and VIMINIT (page 176) variables are set and exported and several aliases (page 312) are established. The final command defines a function (page 315) that swaps the names of two files.

$ cat ~/.bashrc

if [ -f /etc/bashrc ]; then
    source /etc/bashrc  # read global startup file if it exists
fi

set -o noclobber  # prevent overwriting files
unset MAILCHECK  # turn off "you have new mail" notice
export LANG=C  # set LANG variable
export VIMINIT='set ai aw'  # set vim options
alias df='df -h'  # set up aliases
alias rm='rm -i'  # always do interactive rm's
alias lt='ls -ltrh | tail'
alias h='history | tail'
alias ch='chmod 755'
function switch() # a function to exchange the names
{
    # of two files
    local tmp=$$\texttt{switch}
    mv "$1" $tmp
    mv "$2" "$1"
    mv $tmp "$2"
}

(\texttt{Dot}) OR \textbf{source}: Runs a Startup File in the Current Shell

After you edit a startup file such as \texttt{.bashrc}, you do not have to log out and log in again to put the changes into effect. You can run the startup file using the (dot) or \texttt{source} builtin (they are the same command under \texttt{bash}; only \texttt{source} is available under \texttt{tcsh} [page 380]). As with all other commands, the . must be followed by a SPACE on the command line. Using the . or \texttt{source} builtin is similar to running a shell script, except that these commands run the script as part of the current process. Consequently, when you use . or \texttt{source} to run a script, changes you make to variables from within the script affect the shell that you run the script from. You can use the . or \texttt{source} command to run any shell script—not just a startup file—but undesirable side effects (such as changes in the values of shell variables you rely on) may occur. If you ran a startup file as a regular shell script and did not use the . or \texttt{source} builtin, the variables created in the startup file would remain in effect only in the subshell running the script—not in the shell you ran the script from. For more information refer to "Locality of Variables" on page 475.

In the following example, \texttt{.bashrc} sets several variables and sets \texttt{PS1}, the prompt, to the name of the host. The . builtin puts the new values into effect.

\$ cat ~/.bashrc

\begin{verbatim}
export TERM=vt100             # set the terminal type
export PS1="$(hostname -f): " # set the prompt string
export CDPATH=:$HOME          # add HOME to CDPATH string
stty kill '^u'                # set kill line to control-u
\end{verbatim}

\$ . ~/.bashrc

bravo.example.com:

\begin{verbatim}

Commands That Are Symbols

The Bourne Again Shell uses the symbols $, $, $, and $ in a variety of ways. To minimize confusion, Table 8-1 lists the most common use of each of these symbols, even though some of them are not introduced until later.

\end{verbatim}
Table 8-1. Builtin commands that are symbols

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>()</td>
<td>Subshell (page 270)</td>

</tr>
</tbody>
</table>

Redirecting Standard Error

Chapter 5 covered the concept of standard output and explained how to redirect standard output of a command. In addition to standard output, commands can send output to standard error. A command can send error messages to standard error to keep them from getting mixed up with the information it sends to standard output.

Just as it does with standard output, by default the shell sends a command's standard error to the screen. Unless you redirect one or the other, you may not know the difference between the output a command sends to standard output and the output it sends to standard error. This section covers the syntax used by the Bourne Again Shell. See page 349 if you are using the TC Shell.

File descriptors

A file descriptor is the place a program sends its output to and gets its input from. When you execute a program, the process running the program opens three file descriptors: 0 (standard input), 1 (standard output), and 2 (standard error). The redirect output symbol (> [page 116]) is shorthand for 1>, which tells the shell to redirect standard output. Similarly < (page 118) is short for 0<, which redirects standard input. The symbols 2> redirect standard error. For more information refer to "File Descriptors" on page 470.

The following examples demonstrate how to redirect standard output and standard error to different files and to the same file. When you run the `cat` utility with the name of a file that does not exist and the name of a file that does exist, `cat` sends an error message to standard error and copies the file that does exist to standard output. Unless you redirect them, both messages appear on the screen.

```bash
$ cat y
This is y.
$ cat x
```

`cat: x: No such file or directory`

```bash
$ cat x y
```

`cat: x: No such file or directory`
This is y.

When you redirect standard output of a command, output sent to standard error is not affected and still appears on the screen.

```
$ cat x y > hold
```

```
cat: x: No such file or directory
```

```
$ cat hold
```

This is y.

Similarly, when you send standard output through a pipe, standard error is not affected. The following example sends standard output of `cat` through a pipe to `tr` (page 804), which in this example converts lowercase characters to uppercase. The text that `cat` sends to standard error is not translated because it goes directly to the screen rather than through the pipe.

```
$ cat x y | tr "[a-z]" "[A-Z]"
```

```
cat: x: No such file or directory
```

```
THIS IS Y.
```

The following example redirects standard output and standard error to different files. The notation `2>` tells the shell where to redirect standard error (file descriptor 2). The `1>` tells the shell where to redirect standard output (file descriptor 1). You can use `>` in place of `1>`.

```
$ cat x y 1> hold1 2> hold2
```

```
$ cat hold1
```

This is y.

```
$ cat hold2
```

```
cat: x: No such file or directory
```

**Duplicating a file descriptor**

In the next example, `1>` redirects standard output to `hold`. Then `2>&1` declares file descriptor 2 to be a duplicate of file descriptor 1. As a result both standard output and standard error are redirected to `hold`. 
```bash
$ cat x y 1> hold 2>&1
$ cat hold
  
  cat: x: No such file or directory

  This is y.

In the preceding example, 1> hold precedes 2>&1. If they had been listed in the opposite order, standard error
would have been made a duplicate of standard output before standard output was redirected to hold. In that case
only standard output would have been redirected to hold.

The next example declares file descriptor 2 to be a duplicate of file descriptor 1 and sends the output for file
descriptor 1 through a pipe to the tr command.

```bash
$ cat x y 2>&1 | tr "[a-z]" "[A-Z]"
  
  CAT: X: NO SUCH FILE OR DIRECTORY
  THIS IS Y.
  
Sending errors to standard error

You can also use 1>&2 to redirect standard output of a command to standard error. This technique is often used in
shell scripts to send the output of echo to standard error. In the following script, standard output of the first echo
is redirected to standard error:

```bash
$ cat message_demo
  
echo This is an error message. 1>&2
  
echo This is not an error message.

If you redirect standard output of message_demo, error messages such as the one produced by the first echo will
still go to the screen because you have not redirected standard error. Because standard output of a shell script is
frequently redirected to another file, you can use this technique to display on the screen error messages generated by
the script. The links script (page 445) uses this technique. You can also use the exec builtin to create additional file
descriptors and to redirect standard input, standard output, and standard error of a shell script from within the script
(page 491).

The Bourne Again Shell supports the redirection operators shown in Table 8-2.

Table 8-2. Redirection operators
### Writing a Simple Shell Script

A **shell script** is a file that contains commands that the shell can execute. The commands in a shell script can be any commands you can enter in response to a shell prompt. For example, a command in a shell script might run a Linux utility, a compiled program, or another shell script. Like the commands you give on the command line, a command in a shell script can use ambiguous file references and can have its input or output redirected from or to a file or sent through a pipe (page 122). You can also use pipes and redirection with the input and output of the script itself.

In addition to the commands you would ordinarily use on the command line, *control flow* commands (also called *control structures*) find most of their use in shell scripts. This group of commands enables you to alter the order of execution of commands in a script just as you would alter the order of execution of statements using a structured programming language. Refer to "Control Structures" on page 436 (bash) and page 368 (tcsh) for specifics.

The shell interprets and executes the commands in a shell script, one after another. Thus a shell script enables you to simply and quickly initiate a complex series of tasks or a repetitive procedure.

#### chmod: Makes a File Executable

To execute a shell script by giving its name as a command, you must have permission to read and execute the file that contains the script (refer to “Access Permissions” on page 91). Read permission enables you to read the file that holds the script. Execute permission tells the shell and the system that the owner, group, and/or public has permission to execute the file; it implies that the content of the file is executable.

When you create a shell script using an editor, the file does not typically have its execute permission set. The following example shows a file named `whoson` that contains a shell script:

```
$ cat whoson

date

echo "Users Currently Logged In"

who
```

```
$ whoson
```
bash: ./whoson: Permission denied

You cannot execute `whoson` by giving its name as a command because you do not have execute permission for the file. The shell does not recognize `whoson` as an executable file and issues an error message when you try to execute it. When you give the filename as an argument to `bash (bash whoson)`, `bash` takes the argument to be a shell script and executes it. In this case `bash` is executable and `whoson` is an argument that `bash` executes so you do not need to have permission to execute `whoson`. You can do the same with `tcsh` script files.

**tip: Command not found?**

If you get the message

```
$ whoson
bash: whoson: command not found
```

the shell is not set up to search for executable files in the working directory. Give this command instead:

```
$ ./whoson
```

The `./` tells the shell explicitly to look for an executable file in the working directory. To change the environment so that the shell searches the working directory automatically, see page 284.

The `chmod` utility changes the access privileges associated with a file. `Figure 8-1` shows `ls` with the `-l` option displaying the access privileges of `whoson` before and after `chmod` gives execute permission to the file's owner.

*Figure 8-1. Using `chmod` to make a shell script executable*
The first `ls` displays a hyphen (-) as the fourth character, indicating that the owner does not have permission to execute the file. Next `chmod` gives the owner execute permission: The `u+x` causes `chmod` to add (+) execute permission (x) for the owner (u). (The u stands for user, although it means the owner of the file who may be the user of the file at any given time.) The second argument is the name of the file. The second `ls` shows an x in the fourth position, indicating that the owner now has execute permission.

If other users will execute the file, you must also change group and/or public access permissions for the file. Any user must have execute access to use the file's name as a command. If the file is a shell script, the user trying to execute the file must also have read access to the file. You do not need read access to execute a binary executable (compiled program).

The final command in Figure 8-1 shows the shell executing the file when its name is given as a command. For more information refer to "Access Permissions" on page 91 and to `ls` and `chmod` in Part V.

#! Specifies a Shell

You can put a special sequence of characters on the first line of a file to tell the operating system which shell should execute the file. Because the operating system checks the initial characters of a program before attempting to `exec` it, these characters save the system from making an unsuccessful attempt. If #! are the first two characters of a script, the system interprets the characters that follow as the absolute pathname of the utility that should execute the script. This can be the pathname of any program, not just a shell. The following example specifies that `bash` should run the script:

```
$ cat bash_script
#!/bin/bash

echo "This is a Bourne Again Shell script."
```

The #! characters are useful if you have a script that you want to run with a shell other than the shell you are running
the script from. The following example shows a script that should be executed by `tcsh`:

```bash
$ cat tcsh_script
#!/bin/tcsh

echo "This is a tcsh script."

set person = jenny

echo "person is $person"
```

Because of the `#!` line, the operating system ensures that `tcsh` executes the script no matter which shell you run it from.

You can use `ps -f` within a shell script to display the name of the shell that is executing the script. The three lines that `ps` displays in the following example show the process running the parent `bash` shell, the process running the `tcsh` script, and the process running the `ps` command:

```bash
$ cat tcsh_script2
#!/bin/tcsh

ps -f

$ tcsh_script2
```

If you do not follow `#!` with the name of an executable program, the shell reports that it cannot find the command that you asked it to run. You can optionally follow `#!` with SPACES. If you omit the `#!` line and try to run, for example, a `tcsh` script from `bash`, the shell may generate error messages or the script may not run properly.

See page 576 for an example of a stand-alone `sed` script that uses `#!`.

```bash
# Begins A Comment

Comments make shell scripts and all code easier to read and maintain by you and others. The comment syntax is common to both the Bourne Again and the TC Shells.
If a pound sign (#) in the first character position of the first line of a script is not immediately followed by an exclamation point (!) or if a pound sign occurs in any other location in a script, the shell interprets it as the beginning of a comment. The shell then ignores everything between the pound sign and the end of the line (the next NEWLINE character).

Running A Shell Script

fork and exec system calls

A command on the command line causes the shell to **fork** a new process, creating a duplicate of the shell process (a subshell). The new process attempts to **exec** (execute) the command. Like **fork**, the **exec** routine is executed by the operating system (a system call). If the command is a binary executable program, such as a compiled C program, **exec** succeeds and the system overlays the newly created subshell with the executable program. If the command is a shell script, **exec** fails. When **exec** fails, the command is assumed to be a shell script, and the subshell runs the commands in the script. Unlike a login shell, which expects input from the command line, the subshell takes its input from a file: the shell script.

As discussed earlier, if you have a shell script in a file that you do not have execute permission for, you can run the commands in the script by using a **bash** command to **exec** a shell to run the script directly. In the following example, **bash** creates a new shell that takes its input from the file named **whoson**:

```bash
$ bash whoson
```

Because the **bash** command expects to read a file containing commands, you do not need execute permission for **whoson**. (You do need read permission.) Even though **bash** reads and executes the commands in **whoson**, standard input, standard output, and standard error remain connected to the terminal.

Although you can use **bash** to execute a shell script, this technique causes the script to run more slowly than giving yourself execute permission and directly invoking the script. Users typically prefer to make the file executable and run the script by typing its name on the command line. It is also easier to type the name, and this practice is consistent with the way other kinds of programs are invoked (so you do not need to know whether you are running a shell script or another kind of program). However, if **bash** is not your interactive shell or if you want to see how the script runs with different shells, you may want to run a script as an argument to **bash** or **tcsh**.

**caution:** **sh** does not call the original Bourne Shell

The original Bourne Shell was invoked with the command **sh**. Although you can call **bash** with an **sh** command, it is not the original Bourne Shell. The **sh** command (/bin/sh) is a symbolic link to /bin/bash, so it is simply another name for the **bash** command. When you call **bash** using the command **sh**, **bash** tries to mimic the behavior of the original Bourne Shell as closely as possible. It does not always succeed.

Separating and Grouping Commands

Whether you give the shell commands interactively or write a shell script, you must separate commands from one another. This section, which applies to the Bourne Again and the TC Shells, reviews the ways to separate commands that were covered in Chapter 5 and introduces a few new ones.
; AND NEWLINE Separate Commands

The NEWLINE character is a unique command separator because it initiates execution of the command preceding it. You have seen this throughout this book each time you press the RETURN key at the end of a command line.

The semicolon (;) is a command separator that does not initiate execution of a command and does not change any aspect of how the command functions. You can execute a series of commands sequentially by entering them on a single command line and separating each from the next with a semicolon (;). You initiate execution of the sequence of commands by pressing RETURN:

```
$ x ; y ; z
```

If x, y, and z are commands, the preceding command line yields the same results as the next three commands. The difference is that in the next example the shell issues a prompt after each of the commands (x, y, and z) finishes executing, whereas the preceding command line causes the shell to issue a prompt only after z is complete:

```
$ x
$ y
$ z
```

Whitespace

Although the whitespace around the semicolons in the earlier example makes the command line easier to read, it is not necessary. None of the command separators needs to be surrounded by SPACEs or TABs.

\ Continues a Command

When you enter a long command line and the cursor reaches the right side of the screen, you can use a backslash (\) character to continue the command on the next line. The backslash quotes, or escapes, the NEWLINE character that follows it so that the shell does not treat the NEWLINE as a command terminator. Enclosing a backslash within single quotation marks turns off the power of a backslash to quote special characters such as NEWLINE. Enclosing a backslash within double quotation marks has no effect on the power of the backslash.

Although you can break a line in the middle of a word (token), it is typically easier to break a line just before or after whitespace.
You can enter a RETURN in the middle of a quoted string on a command line without using a backslash. The NEWLINE (RETURN) that you enter will then be part of the string:

```
$ echo "Please enter the three values
required to complete the transaction."
Please enter the three values
required to complete the transaction.
```

In the three examples in this section, the shell does not interpret RETURN as a command terminator because it occurs within a quoted string. The > is a secondary prompt indicating that the shell is waiting for you to continue the unfinished command. In the next example, the first RETURN is quoted (escaped) so the shell treats it as a separator and does not interpret it literally.

```
$ echo "Please enter the three values \nrequired to complete the transaction."
Please enter the three values required to complete the transaction.
```

Single quotation marks cause the shell to interpret a backslash literally:

```
$ echo 'Please enter the three values \nrequired to complete the transaction.'
Please enter the three values \nrequired to complete the transaction.
```

The pipe symbol (|) and the background task symbol (&) are also command separators. They do not start execution of a command but do change some aspect of how the command functions. The pipe symbol alters the source of standard input or the destination of standard output. The background task symbol causes the shell to execute the task in the background so you get a prompt immediately and can continue working on other tasks.

Each of the following command lines initiates a single job comprising three tasks:

```
$ x | y | z
```
$ ls -l | grep tmp | less

In the first job, the shell redirects standard output of task $x$ to standard input of task $y$ and redirects $y$'s standard output to $z$'s standard input. Because it runs the entire job in the foreground, the shell does not display a prompt until task $z$ runs to completion: Task $z$ does not finish until task $y$ finishes, and task $y$ does not finish until task $x$ finishes. In the second job, task $x$ is an `ls -l` command, task $y$ is `grep tmp`, and task $z$ is the pager `less`. The shell displays a long (wide) listing of the files in the working directory that contain the string `tmp`, piped through `less`.

The next command line executes tasks $d$ and $e$ in the background and task $f$ in the foreground:

$ d & e & f

[1] 14271

[2] 14272

The shell displays the job number between brackets and the PID (process identification) number for each process running in the background. You get a prompt as soon as $f$ finishes, which may be before $d$ or $e$ finishes.

Before displaying a prompt for a new command, the shell checks whether any background jobs have completed. For each job that has completed, the shell displays its job number, the word `Done`, and the command line that invoked the job; then the shell displays a prompt. When the job numbers are listed, the number of the last job started is followed by a + character and the job number of the previous job is followed by a − character. Any other jobs listed show a SPACE character. After running the last command, the shell displays the following before issuing a prompt:

[1]-  Done                    d
[2]+  Done                    e

The next command line executes all three tasks as background jobs. You get a shell prompt immediately:

$ d & e & f &

[1] 14290

[2] 14291

[3] 14292

You can use pipes to send the output from one task to the next task and an ampersand (`&`) to run the entire job as a background task. Again the prompt comes back immediately. The shell regards the commands joined by a pipe as being a single job. That is, it treats all pipes as single jobs, no matter how many tasks are connected with the pipe (`|`) symbol or how complex they are. The Bourne Again Shell shows only one process placed in the background:

$ d | e | f &
The TC Shell shows three processes (all belonging to job 1) placed in the background:

```
tcsh $ d | e | f &
```

```
[1] 14302 14304 14306
```
optional: ( ) Groups Commands

You can use parentheses to group commands. The shell creates a copy of itself, called a subshell, for each group. It treats each group of commands as a job and creates a new process to execute each command (refer to "Process Structure" on page 293 for more information on creating subshells). Each subshell (job) has its own environment, meaning that it has its own set of variables with values that can differ from those of other subshells.

The following command line executes commands a and b sequentially in the background while executing c in the background. The shell prompt returns immediately.

$ (a ; b) & c &
[1] 15520
[2] 15521

The preceding example differs from the earlier example d & e & f & in that tasks a and b are initiated sequentially, not concurrently.

Similarly the following command line executes a and b sequentially in the background and, at the same time, executes c and d sequentially in the background. The subshell running a and b and the subshell running c and d run concurrently. The prompt returns immediately.

$ (a ; b) & (c ; d) &
[1] 15528
[2] 15529

The next script copies one directory to another. The second pair of parentheses creates a subshell to run the commands following the pipe. Because of these parentheses, the output of the first tar command is available for the second tar command despite the intervening cd command. Without the parentheses, the output of the first tar command would be sent to cd and lost because cd does not process input from standard input. The shell variables $1 and $2 represent the first and second command line arguments (page 481), respectively. The first pair of parentheses, which creates a subshell to run the first two commands, allows users to call cpdir with relative pathnames. Without them the first cd command would change the working directory of the script (and consequently the working directory of the second cd command). With them only the working directory of the subshell is changed.

$ cat cpdir
(cd $1 ; tar -cf - . ) | (cd $2 ; tar -xvf - )

$ cpdir /home/alex/sources /home/alex/memo/biblio

The `cpdir` command line copies the files and directories in the `~/home/alex/sources` directory to the directory named `~/home/alex/memo/biblio`. This shell script is almost the same as using `cp` with the `-r` option. Refer to Part V for more information on `cp` (page 616) and `tar` (page 786).

### Job Control

A job is a command pipeline. You run a simple job whenever you give Linux a command. For example, type `date` on the command line and press RETURN: You have run a job. You can also create several jobs with multiple commands on a single command line:

```
$ find . -print | sort | lpr & grep -l alex /tmp/* > alexfiles &
```

```
[1] 18839

[2] 18876
```

The portion of the command line up to the first `&` is one job consisting of three processes connected by pipes: `find` (page 655), `sort` (page 50), and `lpr` (page 47). The second job is a single process running `grep`. Both jobs have been put into the background by the trailing `&` characters, so `bash` does not wait for them to complete before displaying a prompt.

Using job control you can move commands from the foreground to the background (and vice versa), stop commands temporarily, and list all the commands that are running in the background or stopped.

`jobs`: Lists Jobs

The `jobs` builtin lists all background jobs. The following sequence demonstrates what happens when you give a `jobs` command. Here the `sleep` command runs in the background and creates a background job that `jobs` reports on:

```
$ sleep 60 &
```

```
[1] 7809
```

```
$ jobs
```

```
[1] + Running       sleep 60 &
```

`fg`: Brings a Job to the Foreground
The shell assigns job numbers to commands you run in the background (page 269). Several jobs are started in the background in the next example. For each job the shell lists the job number and PID number immediately, just before it issues a prompt.

```
$ xclock &
[1] 1246
$ date &
[2] 1247
$ Sun Dec 4 11:44:40 PST 2005
[2]+ Done          date
$ find /usr -name ace -print > findout &
[2] 1269
$ jobs
[1]- Running         xclock &
[2]+ Running         find /usr -name ace -print > findout &
```

Job numbers, which are discarded when a job is finished, can be reused. When you start or put a job in the background, the shell assigns a job number that is one more than the highest job number in use.

In the preceding example, the `jobs` command lists the first job, `xclock`, as job 1. The `date` command does not appear in the jobs list because it finished before `jobs` was run. Because the `date` command was completed before `find` was run, the `find` command became job 2.

To move a background job into the foreground, use the `fg` builtin followed by the job number. Alternatively, you can give a percent sign (%) followed immediately by the job number as a command. Either of the following commands moves job 2 into the foreground:

```
$ fg 2
```

```
or

$ %2
```

You can also refer to a job by following the percent sign with a string that uniquely identifies the beginning of the command line used to start the job. Instead of the preceding command, you could have used either `fg %find` or `fg %f` because both uniquely identify job 2. If you follow the percent sign with a question mark and a string, the string can match any part of the command line. In the preceding example, `fg %?ace` also brings job 2 into the foreground.
Often the job you wish to bring into the foreground is the only job running in the background or is the job that `jobs` lists with a plus (+). In these cases you can use `fg` without an argument.

**bg: Sends a Job to the Background**

To move the foreground job to the background, you must first suspend (temporarily stop) the job by pressing the suspend key (usually CONTROL-Z). Pressing the suspend key immediately suspends the job in the foreground. You can then use the `bg` builtin to resume execution of the job in the background.

```
$ bg
```

If a background job attempts to read from the terminal, the shell stops it and notifies you that the job has been stopped and is waiting for input. You must then move the job into the foreground so that it can read from the terminal. The shell displays the command line when it moves the job into the foreground.

```
$ (sleep 5; cat > mytext) &
[1] 1343
$ date
Sun Dec  4 11:58:20 PST 2005
[1]+ Stopped                    ( sleep 5; cat >mytext )
$ fg
( sleep 5; cat >mytext )

Remember to let the cat out!
   CONTROL-D
```

In the preceding example, the shell displays the job number and PID number of the background job as soon as it starts, followed by a prompt. Demonstrating that you can give a command at this point, the user gives the command `date` and its output appears on the screen. The shell waits until just before it issues a prompt (after `date` has finished) to notify you that job 1 is stopped. When you give an `fg` command, the shell puts the job in the foreground and you can enter the input that the command is waiting for. In this case the input needs to be terminated with a CONTROL-D to signify EOF (end of file). The shell then displays another prompt.

The shell keeps you informed about changes in the status of a job, notifying you when a background job starts, completes, or is stopped, perhaps waiting for input from the terminal. The shell also lets you know when a foreground job is suspended. Because notices about a job being run in the background can disrupt your work, the shell delays displaying these notices until just before it displays a prompt. You can set `notify` (page 321) to make the shell display these notices without delay.

If you try to exit from a shell while jobs are stopped, the shell issues a warning and does not allow you to exit. If
you then use `jobs` to review the list of jobs or you immediately try to leave the shell again, the shell allows you to leave and terminates the stopped jobs. Jobs that are running (not stopped) in the background continue to run. In the following example, `find` (job 1) continues to run after the second `exit` terminates the shell, but `cat` (job 2) is terminated:

```
$ find / -size +100k > $HOME/bigfiles 2>&1 &
[1] 1426
$ cat > mytest &
[2] 1428
$ exit
exit
There are stopped jobs.
$ exit
exit

login:

Manipulating the Directory Stack

Both the Bourne Again and the TC Shells allow you to store a list of directories you are working with, enabling you to move easily among them. This list is referred to as a stack. It is analogous to a stack of dinner plates: You typically add plates to and remove plates from the top of the stack, creating a first-in last-out, (FILO) stack.

dirs: Displays the Stack

The `dirs` builtin displays the contents of the directory stack. If you call `dirs` when the directory stack is empty, it displays the name of the working directory:

```
$ dirs
~/literature
```

The `dirs` builtin uses a tilde (~) to represent the name of the home directory. The examples in the next several sections assume that you are referring to the directory structure shown in Figure 8-2.

Figure 8-2. The directory structure in the examples
**pushd**: Pushes a Directory on the Stack

To change directories and at the same time add a new directory to the top of the stack, use the `pushd` (push directory) builtin. In addition to changing directories, the `pushd` builtin displays the contents of the stack. The following example is illustrated in Figure 8-3:

```
$ pushd ../demo
~/demo ~/literature
$ pwd
/home/sam/demo
$ pushd ../names
~/names ~/demo ~/literature
$ pwd
/home/sam/names
```

Figure 8-3. Creating a directory stack
When you use `pushd` without an argument, it swaps the top two directories on the stack and makes the new top directory (which was the second directory) become the new working directory (Figure 8-4):

```
$ pushd
~/demo ~/names ~/literature
$ pwd
/home/sam/demo
```

Using `pushd` in this way, you can easily move back and forth between two directories. You can also use `cd` to change to the previous directory, whether or not you have explicitly created a directory stack. To access another directory in the stack, call `pushd` with a numeric argument preceded by a plus sign. The directories in the stack are numbered starting with the top directory, which is number 0. The following `pushd` command continues with the previous example, changing the working directory to `literature` and moving `literature` to the top of the stack:

```
$ pushd +2
~/literature ~/demo ~/names
```
$ pwd

/home/sam/literature

popd: Pops a Directory Off the Stack

To remove a directory from the stack, use the `popd` (pop directory) builtin. As the following example and Figure 8-5 show, `popd` used without an argument removes the top directory from the stack and changes the working directory to the new top directory:

$ dirs

~/literature ~/demo ~/names

$ popd

~/demo ~/names

$ pwd

/home/sam/demo

Figure 8-5. Using popd to remove a directory from the stack

To remove a directory other than the top one from the stack, use `popd` with a numeric argument preceded by a plus sign. The following example removes directory number 1, `demo`:

$ dirs

~/literature ~/demo ~/names
$ popd +1

~/literature ~/names

Removing a directory other than directory number 0 does not change the working directory.
Parameters and Variables

Variables

Within a shell, a shell parameter is associated with a value that is accessible to the user. There are several kinds of shell parameters. Parameters whose names consist of letters, digits, and underscores are often referred to as shell variables, or simply variables. A variable name must start with a letter or underscore, not with a number. Thus A76, MY_CAT, and _ _ _ X _ _ _ are valid variable names, whereas 69TH_STREET (starts with a digit) and MY-NAME (contains a hyphen) are not.

User-created variables

Shell variables that you name and assign values to are user-created variables. You can change the values of user-created variables at any time, or you can make them readonly so that their values cannot be changed. You can also make user-created variables global. A global variable (also called an environment variable) is available to all shells and other programs you fork from the original shell. One naming convention is to use only uppercase letters for global variables and to use mixed-case or lowercase letters for other variables. Refer to "Locality of Variables" on page 475 for more information on global variables.

To assign a value to a variable in the Bourne Again Shell, use the following syntax:

\[ \text{VARIABLE}=\text{value} \]

There can be no whitespace on either side of the equal sign (=). An example assignment follows:

\$ myvar=abc

Under the TC Shell the assignment must be preceded by the word set and the spaces on either side of the equal sign are optional:

\$ set myvar = abc

The Bourne Again Shell permits you to put variable assignments on a command line. These assignments are local to the command shell; that is, they apply to the command only. The my_script shell script displays the value of TEMPDIR. The following command runs my_script with TEMPDIR set to /home/sam/temp. The echo builtin shows that the interactive shell has no value for TEMPDIR after running my_script. If TEMPDIR had been set in the interactive shell, running my_script in this manner would have had no effect on its value.

\$ cat my_script

echo $TEMPDIR

\$ TEMPDIR=/home/sam/temp my_script

/home/sam/temp
Keyword variables

Keyword shell variables (or simply keyword variables) have special meaning to the shell and usually have short, mnemonic names. When you start a shell (by logging in, for example), the shell inherits several keyword variables from the environment. Among these variables are HOME, which identifies your home directory, and PATH, which determines which directories the shell searches and in what order to locate commands that you give the shell. The shell creates and initializes (with default values) other keyword variables when you start it. Still other variables do not exist until you set them.

You can change the values of most of the keyword shell variables at any time but it is usually not necessary to change the values of keyword variables initialized in the /etc/profile or /etc/csh.cshrc systemwide startup files. If you need to change the value of a bash keyword variable, do so in one of your startup files (for bash see page 257; for tcsh see page 342). Just as you can make user-created variables global, so you can make keyword variables global; this is usually done automatically in the startup files. You can also make a keyword variable readonly.

Positional parameters

Special parameters

The names of one group of parameters do not resemble variable names. Most of these parameters have one-character names (for example, 1, ?, and #) and are referenced (as are all variables) by preceding the name with a dollar sign ($1, $? , and $# ). The values of these parameters reflect different aspects of your ongoing interaction with the shell.

Whenever you give a command, each argument on the command line becomes the value of a positional parameter . Positional parameters (page 480) enable you to access command line arguments, a capability that you will often require when you write shell scripts. The set builtin (page 484) enables you to assign values to positional parameters.

Other frequently needed shell script values, such as the name of the last command executed, the number of command line arguments, and the status of the most recently executed command, are available as special parameters. You cannot assign values to special parameters.

User-Created Variables

The first line in the following example declares the variable named person and initializes it with the value alex (use set person = alex in tcsh):

```sh
$ person=alex
$ echo person
person
```
Because the `echo` builtin copies its arguments to standard output, you can use it to display the values of variables. The second line of the preceding example shows that `person` does not represent `alex`. Instead, the string `person` is echoed as `person`. The shell substitutes the value of a variable only when you precede the name of the variable with a dollar sign ($). The command `echo $person` displays the value of the variable `person`; it does not display `$person` because the shell does not pass `$person` to `echo` as an argument. Because of the leading $, the shell recognizes that `$person` is the name of a variable, substitutes the value of the variable, and passes that value to `echo`. The `echo` builtin displays the value of the variable—not its name—never knowing that you called it with a variable.

Quoting the $

You can prevent the shell from substituting the value of a variable by quoting the leading $. Double quotation marks do not prevent the substitution; single quotation marks or a backslash (\) do.

```
$ echo $person
alex

$ echo "$person"
alex

$ echo '\$person'
$person

$ echo \$person
$person
```

SPACEs

Because they do not prevent variable substitution but do turn off the special meanings of most other characters, double quotation marks are useful when you assign values to variables and when you use those values. To assign a value that contains SPACEs or TABs to a variable, use double quotation marks around the value. Although double quotation marks are not required in all cases, using them is a good habit.

```
$ person="alex and jenny"

$ echo $person
alex and jenny
```

When you reference a variable that contains TABs or multiple adjacent SPACEs, you need to use quotation marks to preserve the spacing. If you do not quote the variable, the shell collapses each string of blank characters into a single SPACE before passing the variable to the utility:

```
$ person=alex and jenny
bash: and: command not found
```

When you execute a command with a variable as an argument, the shell replaces the name of the variable with the value of the variable and passes that value to the program being executed. If the value of the variable contains a special character, such as `*` or `?`, the shell may expand that variable.

Pathname expansion in assignments

The first line in the following sequence of commands assigns the string `alex*` to the variable `memo`. The Bourne Again Shell does not expand the string `alex*` to the variable `memo`. The Bourne Again Shell does not expand the string `alex*` because `bash` does not perform pathname expansion (page 127) when assigning a value to a variable. All shells process a command line in a specific order. Within this order `bash` (but not `tcsh`) expands variables before it interprets commands. In the following `echo` command line, the double quotation marks quote the asterisk (`*`) in the expanded value of `$memo` and prevent `bash` from performing pathname expansion on the expanded `memo` variable before passing its value to the `echo` command:

```
$ memo=alex*
$ echo "$memo"

alex*
```

All shells interpret special characters as special when you reference a variable that contains an unquoted special character. In the following example, the shell expands the value of the `memo` variable because it is not quoted:

```
$ ls
alex.report
```
alex.summary

$ echo $memo

alex.report alex.summary

Here the shell expands $memo to alex*, expands alex* to alex.report and alex.summary, and passes these two values to echo.
optional: Braces

The $VARIABLE$ syntax is a special case of the more general syntax $\{ VARIABLE \}$, in which the variable name is enclosed by ${}$. The braces insulate the variable name. Braces are necessary when catenating a variable value with a string:

$\text{PREF}=\text{counter}$
$\text{WAY}=\text{PREF}\text{clockwise}$
$\text{FAKE}=\text{PREF}\text{feit}$
$\text{echo $WAY$FAKE}$

The preceding example does not work as planned. Only a blank line is output because, although the symbols $\text{PREF}\text{clockwise}$ and $\text{PREF}\text{feit}$ are valid variable names, they are not set. By default the shell evaluates an unset variable as an empty (null) string and displays this value (bash) or generates an error message (tcsh). To achieve the intent of these statements, refer to the $\text{PREF}$ variable using braces:

$\text{PREF}=\text{counter}$
$\text{WAY}=${PREF}$\text{clockwise}$
$\text{FAKE}=${PREF}$\text{feit}$
$\text{echo $WAY$FAKE}$

$\text{counterclockwise counterfeit}$

The Bourne Again Shell refers to the arguments on its command line by position, using the special variables $\$1, \$2, \$3$, and so forth up to $\$9$. If you wish to refer to arguments past the ninth argument, you must use braces: $\{$10$. The name of the command is held in $\$0$ (page 481).

unset: Removes a Variable

Unless you remove a variable, it exists as long as the shell in which it was created exists. To remove the value of a variable but not the variable itself, set the value to null (use set person = in tcsh):

$\text{person=}
You can remove a variable with the `unset` builtin. To remove the variable `person`, give the following command:

```
$ unset person
```

### Variable Attributes

This section discusses attributes and explains how to assign them to variables.

**readonly**: Makes the Value of a Variable Permanent

You can use the `readonly` builtin (not in `tcsh`) to ensure that the value of a variable cannot be changed. The next example declares the variable `person` to be readonly. You must assign a value to a variable before you declare it to be readonly; you cannot change its value after the declaration. When you attempt to unset or change the value of a readonly variable, the shell displays an error message:

```
$ person=jenny
$ echo $person
jenny
$ readonly person
$ person=helen
bash: person: readonly variable
```

If you use the `readonly` builtin without an argument, it displays a list of all readonly shell variables. This list includes keyword variables that are automatically set as readonly as well as keyword or user-created variables that you have declared as readonly. See "Listing variable attributes" on page 282 for an example (`readonly` and `declare` produce the same output).

**declare AND typeset**: Assign Attributes to Variables

The `declare` and `typeset` builtins (two names for the same command, neither of which is available in `tcsh`) set attributes and values for shell variables. Table 8-3 lists five of these attributes.
Table 8-3. Variable attributes (typeset or declare)

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Declares a variable as an array (page 474)</td>
</tr>
<tr>
<td>f</td>
<td>Declares a variable to be a function name (page 315)</td>
</tr>
<tr>
<td>i</td>
<td>Declares a variable to be of type integer (page 283)</td>
</tr>
<tr>
<td>r</td>
<td>Makes a variable readonly; also <code>readonly</code> (page 281)</td>
</tr>
<tr>
<td>x</td>
<td>Exports a variable (makes it global); also <code>export</code> (page 475)</td>
</tr>
</tbody>
</table>

The following commands declare several variables and set some attributes. The first line declares `person1` and assigns it a value of `alex`. This command has the same effect with or without the word `declare`.

```
$ declare person1=alex
```

```
$ declare -r person2=jenny
```

```
$ declare -rx person3=helen
```

```
$ declare -x person4
```

The `readonly` and `export` builtins are synonyms for the commands `declare r` and `declare x`, respectively. It is legal to declare a variable without assigning a value to it, as the preceding declaration of the variable `person4` illustrates. This declaration makes `person4` available to all subshells (makes it global). Until an assignment is made to the variable, it has a null value.

You can list the options to `declare` separately in any order. The following is equivalent to the preceding declaration of `person3`:

```
$ declare -x -r person3=helen
```

Use the `+` character in place of `−` when you want to remove an attribute from a variable. You cannot remove a readonly attribute, however. After the following command is given, the variable `person3` is no longer exported but it is still readonly.

```
$ declare +x person3
```

You can also use `typeset` instead of `declare`.

Listing variable attributes

Without any arguments or options, the `declare` builtin lists all shell variables. The same list is output when you run `set` (page 484) without any arguments.

If you use a `declare` builtin with options but no variable names as arguments, the command lists all shell variables that have the indicated attributes set. For example, the option `−r` with `declare` gives a list of all readonly shell variables. This list is the same as that produced by a `readonly` command without any arguments. After the
declarations in the preceding example have been given, the results are as follows:
$ declare -r
declare -ir EU
declare -ir PP
declare -r SHELLOPTS="braceexpand:emacs:hashall:histexpand:history:..."
declare -ir U
declare -r person2="jenny"
declare -rx person3="helen"
The first five entries are keyword variables that are automatically declared as readonly. Some of these variables are
stored as integers ( i). The a option indicates that BASH_VERSINFO is an array variable; the value of each
element of the array is listed to the right of an equal sign.
Integer

By default the values of variables are stored as strings. When you perform arithmetic on a string variable, the shell
converts the variable into a number, manipulates it, and then converts it back to a string. A variable with the integer
attribute is stored as an integer. Assign the integer attribute as follows:
$ typeset -i COUNT

Keyword Variables
Keyword variables either are inherited or are declared and initialized by the shell when it starts. You can assign
values to these variables from the command line or from a startup file. Typically you want these variables to apply
to all subshells you start as well as to your login shell. For those variables not automatically exported by the shell,
you must use export (bash, page 475) or setenv (tcsh, page 356) to make them available to child shells.
HOME: Your Home Directory

By default your home directory is your working directory when you log in. Your home directory is determined when
you establish your account; its name is stored in the /etc/passwd file.
$ grep sam /etc/passwd
sam:x:501:501:Sam S. x301:/home/sam:/bin/bash


When you log in, the shell inherits the pathname of your home directory and assigns it to the variable `HOME`. When you give a `cd` command without an argument, `cd` makes the directory whose name is stored in `HOME` the working directory:

```
$ pwd
/home/alex/laptop
$ echo $HOME
/home/alex
$ cd
$ pwd
/home/alex
```

This example shows the value of the `HOME` variable and the effect of the `cd` builtin. After you execute `cd` without an argument, the pathname of the working directory is the same as the value of `HOME`: your home directory.

Tilde (~)

The shell uses the value of `HOME` to expand pathnames that use the shorthand tilde (~) notation (page 89) to denote a user's home directory. The following example uses `echo` to display the value of this shortcut and then uses `ls` to list the files in Alex's `laptop` directory, which is a subdirectory of his home directory:

```
$ echo ~
/home/alex
$ ls ~/laptop

tester  count  lineup
```

**PATH: Where the Shell Looks for Programs**

When you give the shell an absolute or relative pathname rather than a simple filename as a command, it looks in the specified directory for an executable file with the specified filename. If the file with the pathname you specified does not exist, the shell reports **command not found**. If the file exists as specified but you do not have execute permission for it, or in the case of a shell script you do not have read and execute permission for it, the shell reports **Permission denied**.

If you give a simple filename as a command, the shell searches through certain directories for the program you want to execute. It looks in several directories for a file that has the same name as the command and that you have
execute permission for (a compiled program) or read and execute permission for (a shell script). The \texttt{PATH} shell variable controls this search.

The default value of \texttt{PATH} is determined when \texttt{bash} or \texttt{tcsh} is compiled. It is not set in a startup file, although it may be modified there. Normally the default specifies that the shell search several system directories used to hold common commands and then search the working directory. These system directories include \texttt{/bin} and \texttt{/usr/bin} and other directories appropriate to the local system. When you give a command, if the shell does not find the executable\texttt{and}, in the case of a shell script, readable\texttt{file} named by the command in any of the directories listed in \texttt{PATH}, the shell generates one of the aforementioned error messages.

\section*{Working directory}

The \texttt{PATH} variable specifies the directories in the order the shell should search them. Each directory must be separated from the next by a colon. The following command sets \texttt{PATH} so that a search for an executable file starts with the \texttt{/usr/local/bin} directory. If it does not find the file in this directory, the shell first looks in \texttt{/bin}, and then in \texttt{/usr/bin}. If the search fails in those directories, the shell looks in the \texttt{bin} director, a subdirectory of the user's home directory. Finally the shell looks in the working directory. Exporting \texttt{PATH} makes its value accessible to subshells:

\begin{verbatim}
$ export PATH=/usr/local/bin:/bin:/usr/bin:~/bin:
\end{verbatim}

A null value in the string indicates the working directory. In the preceding example, a null value (nothing between the colon and the end of the line) appears as the last element of the string. The working directory is represented by a leading colon (not recommended; see the following security tip), a trailing colon (as in the example), or two colons next to each other anywhere in the string. You can also represent the working directory explicitly with a period (\texttt{.}).

See " \texttt{PATH} " on page 363 for a \texttt{tcsh} example. Because Linux stores many executable files in directories named \texttt{bin} (\texttt{binary}), users typically put their own executable files in their own \texttt{~/bin} directories. If you put your own \texttt{bin} directory at the end of your \texttt{PATH}, as in the preceding example, the shell looks there for any commands that it cannot find in directories listed earlier in \texttt{PATH}.

\subsection*{security: \texttt{PATH} and security}

Do not put the working directory first in \texttt{PATH} when security is a concern. If you are running as Superuser, you should never put the working directory first in \texttt{PATH}. It is common for Superuser \texttt{PATH} to omit the working directory entirely. You can always execute a file in the working directory by prepending \texttt{./} to the name: \texttt{./ls}.

Putting the working directory first in \texttt{PATH} can create a security hole. Most people type \texttt{ls} as the first command when entering a directory. If the owner of a directory places an executable file named \texttt{ls} in the directory, and the working directory appears first in a user's \texttt{PATH}, the user giving an \texttt{ls} command from the directory executes the \texttt{ls} program in the working directory instead of the system \texttt{ls} utility, possibly with undesirable results.

If you want to add directories to \texttt{PATH}, you can reference the old value of the \texttt{PATH} variable while you are setting \texttt{PATH} to a new value (but see the preceding security tip). The following command adds \texttt{/usr/X11R6/bin} to the beginning of the current \texttt{PATH} and \texttt{/usr/local/bin} and the working directory to the end:

\begin{verbatim}
$ PATH=/usr/X11R6/bin:$PATH:/usr/local/bin:
\end{verbatim}
**MAIL: Where Your Mail Is Kept**

The `MAIL` variable (mail under `tcsh`) contains the pathname of the file that holds your mail (your mailbox, usually `/var/spool/mail/` name, where `name` is your login name). If `MAIL` is set and `MAILPATH` (next) is not set, the shell informs you when mail arrives in the file specified by `MAIL`. In a graphical environment you can unset `MAIL` so that the shell does not display mail reminders in a terminal emulator window (assuming you are using a graphical mail program).

The `MAILPATH` variable (not available under `tcsh`) contains a list of filenames separated by colons. If this variable is set, the shell informs you when any one of the files is modified (for example, when mail arrives). You can follow any of the filenames in the list with a question mark (?), followed by a message. The message replaces the `you have mail` message when you get mail while you are logged in.

The `MAILCHECK` variable (not available under `tcsh`) specifies how often, in seconds, the shell checks for new mail. The default is 60 seconds. If you set this variable to zero, the shell checks before each prompt.

**PS1: User Prompt (Primary)**

The default Bourne Again Shell prompt is a dollar sign ($). When you run `bash` as `root`, you may have a pound sign (#) prompt. The `PS1` variable (prompt under `tcsh`, page 363) holds the prompt string that the shell uses to let you know that it is waiting for a command. When you change the value of `PS1` or `prompt`, you change the appearance of your prompt.

You can customize the prompt displayed by `PS1`. For example, the assignment

```bash
$ PS1="[\u@\h \W \!]$ 
```

displays the following prompt:

```
[user@host directory event]$ 
```

where `user` is the username, `host` is the hostname up to the first period, `directory` is the basename of the working directory, and `event` is the event number of the current command.

If you are working on more than one system, it can be helpful to incorporate the system name into your prompt. For example, you might change the prompt to the name of the system you are using, followed by a colon and a SPACE (a SPACE at the end of the prompt makes the commands that you enter after the prompt easier to read):

```bash
$ PS1="$(hostname): "
```

```
bravo.example.com:  echo test
test
bravo.example.com: 
```

Use the following command under tcsh:

```
tcsh $ set prompt = "`hostname`: "
```

The first example that follows changes the prompt to the name of the local host, a SPACE, and a dollar sign (or, if the user is running as root, a pound sign). The second example changes the prompt to the time followed by the name of the user. The third example changes the prompt to the one used in this book (a pound sign for root and a dollar sign otherwise):

```
$ PS1='{\h \$ '  
bravo $

$ PS1='{\@ \u \$ '  
09:44 PM alex $

$ PS1='{\$ '  
$
```

Table 8-4 describes some of the symbols you can use in PS1. For a complete list of special characters you can use in the prompt strings, open the bash man page and search for the second occurrence of PROMPTING (give the command `/PROMPTING` and then press n).

<table>
<thead>
<tr>
<th>Symbol</th>

</tr>
</tbody>
</table>

**PS2: User Prompt (Secondary)**
Prompt String 2 is a secondary prompt that the shell stores in PS2 (not under tcsh). On the first line of the next example, an unclosed quoted string follows echo. The shell assumes that the command is not finished and, on the second line, gives the default secondary prompt (>). This prompt indicates that the shell is waiting for the user to continue the command line. The shell waits until it receives the quotation mark that closes the string and then executes the command:

```
$ echo "demonstration of prompt string

> 2"

demonstration of prompt string

2

$ PS2="secondary prompt: "

$ echo "this demonstrates

secondary prompt: prompt string 2"

this demonstrates

prompt string 2
```

The second command changes the secondary prompt to secondary prompt: followed by a SPACE. A multiline echo demonstrates the new prompt.

**PS3**: Menu Prompt

PS3 holds the menu prompt for the select control structure (page 467).

**PS4**: Debugging Prompt

PS4 holds the bash debugging symbol (page 449).

**caution: Be careful when changing IFS**

Changing IFS has a variety of side effects so work cautiously. You may find it useful to first save the value of IFS before changing it; you can easily then restore the original value if you get unexpected results. Alternatively, you can fork a new shell with a bash command before experimenting with IFS; if you get into trouble, you can exit back to the old shell, where IFS is working properly. You can also set IFS to its default value with the following command:

```
$ IFS=' \
'
**IFS:** Separates Input Fields (Word Splitting)

The **IFS** (Internal Field Separator) shell variable (not under **tcsh**) specifies the characters that you can use to separate arguments on a command line and has the default value of SPACE TAB NEWLINE. Regardless of the value of **IFS**, you can always use one or more SPACE or TAB characters to separate arguments on the command line, provided that these characters are not quoted or escaped. When you assign **IFS** character values, these characters can also separate fields but only if they undergo expansion. This type of interpretation of the command line is called **word splitting**.

The following example demonstrates how setting **IFS** can affect the interpretation of a command line:

```
$ a=w:x:y:z
$ cat $a
  cat: w:x:y:z: No such file or directory
$ IFS=":"
$ cat $a
  cat: w: No such file or directory
  cat: x: No such file or directory
  cat: y: No such file or directory
  cat: z: No such file or directory
```

The first time **cat** is called, the shell expands the variable **a**, interpreting the string **w:x:y:z** as a single word to be used as the argument to **cat**. The **cat** utility cannot find a file named **w:x:y:z** and reports an error for that filename. After **IFS** is set to a colon (:), the shell expands the variable **a** into four words, each of which is an argument to **cat**. Now **cat** reports an error for four separate files: **w**, **x**, **y**, and **z**. Word splitting based on the colon (:) takes place only after the variable **a** is expanded.

The shell splits all expanded words on a command line according to the separating characters found in **IFS**. When there is no expansion, there is no splitting. Consider the following commands:

```
$ IFS="p"
$ export VAR
```

Although **IFS** is set to **p**, the **p** on the **export** command line is not expanded so the word **export** is not split.

The next example uses variable expansion in an attempt to produce an **export** command:

```
$ IFS="p"
```

$ aa=export
$ echo $aa
export

This time expansion occurs so that the character `p` in the token `export` is interpreted as a separator as the preceding `echo` command shows. Now when you try to use the value of the `aa` variable to export the `VAR` variable, the shell parses the `$aa VAR` command line as `ex ort VAR`. The effect is that the command line starts the `ex` editor with two filenames: `ort` and `VAR`.

$ $aa VAR
2 files to edit
"ort" [New File]
Entering Ex mode. Type "visual" to go to Normal mode.

:q

E173: 1 more file to edit

:q

$

If you unset `IFS`, only SPACEs and TABs work as field separators.

**CDPATH: Broadens the Scope of cd**

The `CDPATH` variable (cdpath under `tcsh`) allows you to use a simple filename as an argument to the `cd` builtin to change the working directory to a directory other than a child of the working directory. If you have several directories you like to work out of, this variable can speed things up and save you the tedium of using `cd` with longer pathnames to switch among them.

When `CDPATH` or `cdpath` is not set and you specify a simple filename as an argument to `cd`, `cd` searches the working directory for a subdirectory with the same name as the argument. If the subdirectory does not exist, `cd` displays an error message. When `CDPATH` or `cdpath` is set, `cd` searches for an appropriately named subdirectory in the directories in the `CDPATH` list. If `cd` finds one, that directory becomes the working directory. With `CDPATH` or `cdpath` set, you can use `cd` and a simple filename to change the working directory to a child of any of the directories listed in `CDPATH` or `cdpath`.

The `CDPATH` or `cdpath` variable takes on the value of a colon-separated list of directory pathnames (similar to the `PATH` variable). It is usually set in the `~/.bash_profile` (`bash`) or `~/.tcshrc` (`tcsh`) startup file with a command line such as the following:

```bash
export CDPATH=$HOME:$HOME/literature
```
Use the following format for `tcsh`:

```
setenv cdpath $HOME:\:$HOME/literature
```

These commands cause `cd` to search your home directory, the `literature` directory, and then the working directory when you give a `cd` command. If you do not include the working directory in `CDPATH` or `cdpath`, `cd` searches the working directory if the search of all the other directories in `CDPATH` or `cdpath` fails. If you want `cd` to search the working directory first (which you should never do when you are logged in as `root` refer to the security tip on page 285), include a null string, represented by two colons (`::`), as the first entry in `CDPATH`:

```
export CDPATH=::$HOME:$HOME/literature
```

If the argument to the `cd` builtin is an absolute filename—one starting with a slash (`/`) the shell does not consult `CDPATH` or `cdpath`.

**Keyword Variables: A Summary**

Table 8-5 lists the `bash` keyword variables.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>BASH_ENV</td>
<td>The pathname of the startup file for noninteractive shells (page 258)</td>
</tr>
</tbody>
</table>
Variable | Value
---|---
**PATH** | A colon-separated list of directory pathnames that **bash** looks for commands in (page 284)
**PROMPT_COMMAND** | A command that **bash** executes just before it displays the primary prompt
**PS1** | Prompt String 1; the primary prompt (default: "\s\v\$ "; page 286)
**PS2** | Prompt String 2; the secondary prompt (default: ‘> ’; page 287)
**PS3** | The prompt issued by **select** (page 466)
**PS4** | The **bash** debugging symbol (page 449)
**REPLY** | Holds the line that **read** accepts (page 488); also used by **select** (page 466)

**Special Characters**

Table 8-6 lists most of the characters that are special to the **bash** and **tcsh** shells.

### Table 8-6. Shell special characters

<table>

<td>Evaluates an arithmetic expression (page 327)</td>
</tr>
</tbody>
</table>
Processes

A process is the execution of a command by Linux. The shell that starts when you log in is a command, or a process, like any other. When you give the name of a Linux utility on the command line, you initiate a process. When you run a shell script, another shell process is started and additional processes are created for each command in the script. Depending on how you invoke the shell script, the script is run either by the current shell or, more typically, by a subshell (child) of the current shell. A process is not started when you run a shell builtin, such as cd.

Process Structure

fork system call

Like the file structure, the process structure is hierarchical, with parents, children, and even a root. A parent process forks a child process, which in turn can fork other processes. (The term fork indicates that, as with a fork in the road, one process turns into two. Initially the two forks are identical except that one is identified as the parent and one as the child. You can also use the term spawn; the words are interchangeable.) The operating system routine, or system call, that creates a new process is named fork.

When Linux begins execution when a system is started, it starts init, a single process called a spontaneous process, with PID number 1. This process holds the same position in the process structure as the root directory does in the file structure: It is the ancestor of all processes that the system and users work with. When the system is in multiuser mode, init runs getty or mingetty processes, which display login: prompts on terminals and virtual consoles. When someone responds to the prompt and presses RETURN, getty hands control over to a utility named login, which checks the username and password combination. After the user logs in, the login process becomes the user's shell process.

Process Identification

PID number

Linux assigns a unique PID (process identification) number at the inception of each process. As long as a process exists, it keeps the same PID number. During one session the same process is always executing the login shell. When you fork a new process—for example, when you use an editor—the PID number of the new (child) process is different from that of its parent process. When you return to the login shell, it is still being executed by the same process and has the same PID number as when you logged in.

The following example shows that the process running the shell forked (is the parent of) the process running ps (page 127). When you call it with the -f option, ps displays a full listing of information about each process. The line of the ps display with bash in the CMD column refers to the process running the shell. The column headed by PID identifies the PID number. The column headed PPID identifies the PID number of the parent process. From the PID and PPID columns you can see that the process running the shell (PID 21341) is the parent of the process running sleep (PID 22789). The parent PID number of sleep is the same as the PID number of the shell (21341).

$ sleep 10 &

[1] 22789

$ ps -f
Refer to page 746 for more information on `ps` and the columns it displays with the `f` option. A second pair of `sleep` and `ps -f` commands shows that the shell is still being run by the same process but that it forked another process to run `sleep`:

```
$ sleep 10 &
[1] 22791
$ ps -f
```

You can also use `pstree` (or `ps -f forest`, with or without the `e` option) to see the parent-child relationship of processes. The next example shows the `-p` option to `pstree`, which causes it to display PID numbers:

```
$ pstree -p
init(1)-+-acpid(1395)
     |     |+-atd(1758)
     |     |+-crond(1702)
     ...
     |+-kdeinit(2223)-+-firefox(8914)--run-mozilla.sh(8920)--firefox-bin(8925)
     |     |     |     |+-gaim(2306)
     |     |     |     |     |+-gqview(14062)
     |     |     |     |     |     |+-kdeinit(2228)
     |     |     |     |     |     |     |+-kdeinit(2294)
```
The preceding output is abbreviated. The line that starts with `kdeinit` shows a graphical user running many processes, including `firefox`, `gaim`, and `oclock`. The line that starts with `login` shows a textual user running `sleep` in the background while running `pstree` in the foreground. Refer to "$S: PID Number: PID Number" on page 478 for a description of how to instruct the shell to report on PID numbers.

### Executing A Command

#### fork and sleep

When you give the shell a command, it usually forks (spawns) a child process to execute the command. While the child process is executing the command, the parent process `sleeps`. While a process is sleeping, it does not use any computer time but remains inactive, waiting to wake up. When the child process finishes executing the command, it tells its parent of its success or failure via its exit status and then dies. The parent process (which is running the shell) wakes up and prompts for another command.

#### Background process

When you run a process in the background by ending a command with an ampersand (&), the shell forks a child process without going to sleep and without waiting for the child process to run to completion. The parent process, which is executing the shell, reports the job number and PID number of the child and prompts for another command. The child process runs in the background, independent of its parent.

#### Builtins

Although the shell forks a process to run most of the commands you give it, some commands are built into the shell. The shell does not need to fork a process to run builtins. For more information refer to "Builtins" on page 132.
Variables

Within a given process, such as your login shell or a subshell, you can declare, initialize, read, and change variables. By default, however, a variable is local to a process. When a process forks a child process, the parent does not pass the value of a variable to the child. You can make the value of a variable available to child processes (global) by using the `export` builtin under `bash` (page 475) or the `setenv` builtin under `tcsh` (page 356).
History

The history mechanism, a feature adapted from the C Shell, maintains a list of recently issued command lines, also called events, providing a quick way to reexecute any of the events in the list. This mechanism also enables you to execute variations of previous commands and to reuse arguments from them. You can replicate complicated commands and arguments that you used earlier in this login session or in a previous one and enter a series of commands that differ from one another in minor ways. The history list also serves as a record of what you have done. It can prove helpful when you have made a mistake and are not sure what you did or when you want to keep a record of a procedure that involved a series of commands.

The history builtin (both in bash and tcsh) displays the history list. If it does not, you need to set some variables.

**tip: history can help track down mistakes**

When you have made a command line mistake (not an error within a script or program) and are not sure what you did wrong, look at the history list to review your recent commands. Sometimes this list can help you figure out what went wrong and how to fix things.

Variables That Control History

The TC Shell's history mechanism is similar to bash's but uses different variables and has other differences. See page 344 for more information.

The value of the HISTSIZE variable determines the number of events preserved in the history list during a session. A value in the range of 100 to 1,000 is normal.

When you exit from the shell, the most recently executed commands are saved in the file given by the HISTFILE variable (the default is ~/.bash_history). The next time you start the shell, this file initializes the history list. The value of the HISTFILESIZE variable determines the number of lines of history saved in HISTFILE (not necessarily the same as HISTSIZE). HISTSIZE holds the number of events remembered during a session, HISTFILESIZE holds the number remembered between sessions, and the file designated by HISTFILE holds the history list. See Table 8-7.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Default</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>HISTSIZE</td>
<td>500 events</td>
<td>Maximum number of events saved during a session</td>
</tr>
<tr>
<td>HISTFILE</td>
<td>~/.bash_history</td>
<td>Location of the history file</td>
</tr>
<tr>
<td>HISTFILESIZE</td>
<td>500 events</td>
<td>Maximum number of events saved between sessions</td>
</tr>
</tbody>
</table>

Event number

The Bourne Again Shell assigns a sequential event number to each command line. You can display this event number as part of the bash prompt by including \ in PS1 (page 286). Examples in this section show numbered prompts when they help to illustrate the behavior of a command.

Give the following command manually or place it in ~/.bash_profile (to affect future sessions) to establish a history list of the 100 most recent events:
$ HISTSIZE=100

The following command causes bash to save the 100 most recent events across login sessions:

$ HISTFILESIZE=100

After you set HISTFILESIZE, you can log out and log in again, and the 100 most recent events from the previous login session will appear in your history list.

Give the command history to display the events in the history list. The list of events is ordered with oldest events at the top of the list. A tcsh history list includes the time the command was executed. The following history list includes a command to modify the bash prompt so that it displays the history event number. The last event in the history list is the history command that displayed the list.

32 $ history | tail

   23 PS1="\! bash$ "
   24 ls -l
   25 cat temp
   26 rm temp
   27 vim memo
   28 lpr memo
   29 vim memo
   30 lpr memo
   31 rm memo
   32 history | tail

As you run commands and your history list becomes longer, it may run off the top of the screen when you use the history builtin. Pipe the output of history through less to browse through it, or give the command history 10 to look at the ten most recent commands.

Reexecuting and Editing Commands

You can reexecute any event in the history list. This feature can save you time, effort, and aggravation. Not having to reenter long command lines allows you to reexecute events more easily, quickly, and accurately than you could if you had to retype the entire command line. You can recall, modify, and reexecute previously executed events in three ways: You can use the fc builtin (covered next); the exclamation point commands (page 300); or the Readline Library, which uses a one-line vi- or emacs-like editor to edit and execute events (page 305).
**tip: Which method to use?**

If you are more familiar with **vi** or **emacs** and less familiar with the C or TC Shell, use **fc** or the Readline Library. If you are more familiar with the C or TC Shell and less familiar with **vi** and **emacs**, use the exclamation point commands. If it is a toss-up, try the Readline Library; it will benefit you in other areas of Linux more than learning the exclamation point commands will.

**fc: Displays, Edits, and Reexecutes Commands**

The **fc** (fix command) builtin (not in **tcsh**) enables you to display the history list and to edit and reexecute previous commands. It provides many of the same capabilities as the command line editors.

**Viewing the History List**

When you call **fc** with the ```l``` option, it displays commands from the history list. Without any arguments, **fc l** lists the 16 most recent commands in a numbered list, with the oldest appearing first:

```
$ fc -l
1024       cd
1025       view calendar
1026       vim letter.adams01
1027       aspell -c letter.adams01
1028       vim letter.adams01
1029       lpr letter.adams01
1030       cd ../memos
1031       ls
1032       rm *0405
1033       fc -l
1034       cd
1035       whereis aspell
1036       man aspell
1037       cd /usr/share/doc/*aspell*
1038       pwd
1039       ls
```
The `fc` builtin can take zero, one, or two arguments with the `l` option. The arguments specify the part of the history list to be displayed:

```
fc l [ first [ last ]]
```

The `fc` builtin lists commands beginning with the most recent event that matches `first`. The argument can be an event number, the first few characters of the command line, or a negative number, which is taken to be the `n`th previous command. If you provide `last`, `fc` displays commands from the most recent event that matches `first` through the most recent event that matches `last`. The next command displays the history list from event 1030 through event 1035:

```
$ fc -l 1030 1035
```

```
1030     cd ../memos
1031     ls
1032     rm *0405
1033     fc -l
1034     cd
1035     whereis aspell
```

The following command lists the most recent event that begins with `view` through the most recent command line that begins with `whereis`:

```
$ fc -l view whereis
```

```
1025     view calendar
1026     vim letter.adams01
1027     aspell -c letter.adams01
1028     vim letter.adams01
1029     lpr letter.adams01
1030     cd ../memos
```
To list a single command from the history list, use the same identifier for the first and second arguments. The following command lists event 1027:

```
$ fc -l 1027 1027
1027     aspell -c letter.adams01
```

Editing and Reexecuting Previous Commands

You can use `fc` to edit and reexecute previous commands.

```
f [e editor] [first [last]]
```

When you call `fc` with the `e` option followed by the name of an editor, `fc` calls the editor with event(s) in the Work buffer. Without `first` and `last`, `fc` defaults to the most recent command. The next example invokes the `vi(m)` editor to edit the most recent command:

```
$ fc -e vi
```

The `fc` builtin uses the stand-alone `vi(m)` editor. If you set the `FCEDIT` variable, you do not need to use the `e` option to specify an editor on the command line. Because the value of `FCEDIT` has been changed to `/usr/bin/emacs` and `fc` has no arguments, the following command edits the most recent command with the `emacs` editor:

```
$ export FCEDIT=/usr/bin/emacs
$ fc
```
If you call it with a single argument, `fc` invokes the editor on the specified command. The following example starts the editor with event 21 in the Work buffer. When you exit from the editor, the shell executes the command:

```
$ fc 21
```

Again you can identify commands with numbers or by specifying the first few characters of the command name. The following example calls the editor to work on events from the most recent event that begins with the letters `vim` through event 206:

```
$ fc vim 206
```

**caution: Clean up the `fc` buffer**

When you execute an `fc` command, the shell executes whatever you leave in the editor buffer, possibly with unwanted results. If you decide you do not want to execute a command, delete everything from the buffer before you exit from the editor.

Reexecuting Commands Without Calling the Editor

You can reexecute previous commands without going into an editor. If you call `fc` with the `-s` option, it skips the editing phase and reexecutes the command. The following example reexecutes event 1029:

```
$ fc -s 1029
lpr letter.adams01
```

The next example reexecutes the previous command:

```
$ fc -s
```

When you reexecute a command you can tell `fc` to substitute one string for another. The next example substitutes the string `john` for the string `adams` in event 1029 and executes the modified event:

```
$ fc -s adams=john 1029
lpr letter.john01
```

Using an Exclamation Point (!) to Reference Events

The C Shell history mechanism uses an exclamation point to reference events and is available under `bash` and `tcsh`. It is frequently more cumbersome to use than `fc` but nevertheless has some useful features. For example, the
!! command reexecutes the previous event, and the !$ token represents the last word on the previous command line.

You can reference an event by using its absolute event number, its relative event number, or the text it contains. All references to events, called event designators, begin with an exclamation point (!). One or more characters follow the exclamation point to specify an event.

You can put history events anywhere on a command line. To escape an exclamation point so that it is treated literally instead of as the start of a history event, precede it with a backslash (\) or enclose it within single quotation marks.

**Event Designators**

An event designator specifies a command in the history list. See Table 8-8 on page 301 for a list of event designators.

<table>
<thead>
<tr>
<th>Designator</th>
<th>Meaning</th>
</tr>
</thead>
</table>
| !          | Starts a history event unless followed immediately by SPACE, NEWLINE, =, or (.
| !!         | The previous command. |
| !n         | Command number n in the history list. |
| !n         | The n-th preceding command. |
| !string    | The most recent command line that started with string. |
| !? string [?] | The most recent command that contained string. The last ? is optional. |
| !#         | The current command (as you have it typed so far). |
| {! event } | The event is an event designator. The braces isolate event from the surrounding text. For example, !{3}3 is the third most recently executed command followed by a 3. |

!! reexecutes the previous event

You can always reexecute the previous event by giving a !! command. In the following example, event 45 reexecutes event 44:

```
44 $ ls -l text
-rw-rw-r-- 1 alex group 45 Apr 30 14:53 text
45 $ !!
ls -l text
-rw-rw-r-- 1 alex group 45 Apr 30 14:53 text
```

The !! command works whether or not your prompt displays an event number. As this example shows, when you use the history mechanism to reexecute an event, the shell displays the command it is reexecuting.

! n event number
A number following an exclamation point refers to an event. If that event is in the history list, the shell executes it. Otherwise, the shell displays an error message. A negative number following an exclamation point references an event relative to the current event. For example, the command \texttt{! \ 3} refers to the third preceding event. After you issue a command, the relative event number of a given event changes (event \texttt{3} becomes event \texttt{4}). Both of the following commands reexecute event 44:

51 \$ \texttt{!44}

\texttt{ls -l text}

\texttt{-rw-rw-r-- 1 alex group 45 Nov 30 14:53 text}

52 \$ \texttt{!-8}

\texttt{ls -l text}

\texttt{-rw-rw-r-- 1 alex group 45 Nov 30 14:53 text}

\texttt{! string event text}

When a string of text follows an exclamation point, the shell searches for and executes the most recent event that \textit{began} with that string. If you enclose the string between question marks, the shell executes the most recent event that \textit{contained} that string. The final question mark is optional if a RETURN would immediately follow it.

68 \$ \texttt{history 10}

59 \texttt{ls -l text*}

60 \texttt{tail text5}

61 \texttt{cat text1 text5 > letter}

62 \texttt{vim letter}

63 \texttt{cat letter}

64 \texttt{cat memo}

65 \texttt{lpr memo}

66 \texttt{pine jenny}

67 \texttt{ls -l}

68 \texttt{history}

69 \$ \texttt{!1}

\texttt{ls -l}
...  
70 $ !lpr  
lpr memo  
71 $ !?letter?  
cat letter  
...
optional: WORD DESIGNATORS

A word designator specifies a word or series of words from an event. Table 8-9 on page 303 lists word designators.

Table 8-9. Word designators

<table>
<thead>
<tr>
<th>Designator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>$n$</td>
<td>The $n$th word. Word 0 is normally the command name.</td>
</tr>
<tr>
<td>^</td>
<td>The first word (after the command name).</td>
</tr>
<tr>
<td>$</td>
<td>The last word.</td>
</tr>
<tr>
<td>$m\text{n}$</td>
<td>All words from word number $m$ through word number $n$; $m$ defaults to 0 if you omit it (0$n$).</td>
</tr>
<tr>
<td>$n^*$</td>
<td>All words from word number $n$ through the last word.</td>
</tr>
<tr>
<td>*</td>
<td>All words except the command name. The same as 1*.</td>
</tr>
<tr>
<td>%</td>
<td>The word matched by the most recent ?string ? search.</td>
</tr>
</tbody>
</table>

The words are numbered starting with 0 (the first word on the line, usually the command), continuing with 1 (the first word following the command), and going through $n$ (the last word on the line).

To specify a particular word from a previous event, follow the event designator (such as !14) with a colon and the number of the word in the previous event. For example, !14:3 specifies the third word following the command from event 14. You can specify the first word following the command (word number 1) by using a caret (^) and the last word by using a dollar sign ($). You can specify a range of words by separating two word designators with a hyphen.

72 $ echo apple grape orange pear
apple grape orange pear

73 $ echo !72:2
echo grape
grape

74 $ echo !72:^
echo apple
apple

75 $ !72:0 !72:$
echo pear
pear
As the next example shows, $!$ refers to the last word of the previous event. You can use this shorthand to edit, for example, a file you just displayed with `cat`:

```
$ cat report.718
...
$ vim !$
vim report.718
...
```

If an event contains a single command, the word numbers correspond to the argument numbers. If an event contains more than one command, this correspondence does not hold true for commands after the first. In the following example event 78 contains two commands separated by a semicolon so that the shell executes them sequentially; the semicolon is word number 5.

```
78 $ !72 ; echo helen jenny barbara
echo apple grape orange pear ; echo helen jenny barbara
apple grape orange pear
helen jenny barbara
79 $ echo !78:7
echo helen
helen
80 $ echo !78:4-7
echo pear ; echo helen
```
MODIFIERS

On occasion you may want to change an aspect of an event you are reexecuting. Perhaps you entered a complex command line with a typo or incorrect pathname or you want to specify a different argument. You can modify an event or a word of an event by putting one or more modifiers after the word designator, or after the event designator if there is no word designator. Each modifier must be preceded by a colon (:).

Substitute modifier

The substitute modifier is more complex than the other modifiers. The following example shows the substitute modifier correcting a typo in the previous event:

```
$ car /home/jenny/memo.0507 /home/alex/letter.0507
bash: car: command not found
$ !!:s/car/cat

$ cat /home/jenny/memo.0507 /home/alex/letter.0507
...
```

The substitute modifier has the following syntax:

```
[g]s/old/new/
```

where `old` is the original string (not a regular expression), and `new` is the string that replaces `old`. The substitute modifier substitutes the first occurrence of `old` with `new`. Placing a `g` before the `s` (as in `gs/old/new/`) causes a global substitution, replacing all occurrences of `old`. The `/` is the delimiter in the examples but you can use any character that is not in either `old` or `new`. The final delimiter is optional if a RETURN would immediately follow it. As with the Vim Substitute command, the history mechanism replaces an ampersand (`&`) in `new` with `old`. The shell replaces a null old string (`s//new/`) with the previous old string or string within a command that you searched for with `?string?`

Quick substitution
An abbreviated form of the substitute modifier is *quick substitution*. Use it to reexecute the most recent event while changing some of the event text. The quick substitution character is the caret (^). For example, the command

```
$ ^old^new^
```

produces the same results as

```
$ !!:s/old/new/
```

Thus substituting `cat` for `car` in the previous event could have been entered as

```
$ ^car^cat
```

cat /home/jenny/memo.0507 /home/alex/letter.0507
...

You can omit the final caret if it would be followed immediately by a RETURN. As with other command line substitutions, the shell displays the command line as it appears after the substitution.

Other modifiers

Modifiers (other than the substitute modifier) perform simple edits on the part of the event that has been selected by the event designator and the optional word designators. You can use multiple modifiers, each preceded by a colon (:)..

The following series of commands uses `ls` to list the name of a file, repeats the command without executing it (`p` modifier), and repeats the last command, removing the last part of the pathname (`h` modifier) again without executing it:

```
$ ls /etc/sysconfig/harddisks
/etc/sysconfig/harddisks
$ !!:p
ls /etc/sysconfig/harddisks
$ !!:h:p
ls /etc/sysconfig
```
Table 8-10 lists event modifiers other than the substitute modifier.

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>e</td>
<td>(extension) Removes all but the filename extension</td>
</tr>
<tr>
<td>h</td>
<td>(head) Removes the last part of a pathname</td>
</tr>
<tr>
<td>p</td>
<td>(print-not) Displays the command, but does not execute it</td>
</tr>
<tr>
<td>q</td>
<td>(quote) Quotes the substitution to prevent further substitutions on it</td>
</tr>
<tr>
<td>r</td>
<td>(root) Removes the filename extension</td>
</tr>
<tr>
<td>t</td>
<td>(tail) Removes all elements of a pathname except the last</td>
</tr>
<tr>
<td>x</td>
<td>Like q but quotes each word in the substitution individually</td>
</tr>
</tbody>
</table>

The Readline Library

Command line editing under the Bourne Again Shell is implemented through the Readline Library, which is available to any application written in C. Any application that uses the Readline Library supports line editing that is consistent with that provided by bash. Programs that use the Readline Library, including bash, read ~/.inputrc (page 309) for key binding information and configuration settings. The `noediting` command line option turns off command line editing in bash.

vi mode

You can choose one of two editing modes when using the Readline Library in bash: emacs or vi(m). Both modes provide many of the commands available in the stand-alone versions of the vi(m) and emacs editors. You can also use the ARROW keys to move around. Up and down movements move you backward and forward through the history list. In addition, Readline provides several types of interactive word completion (page 307). The default mode is emacs; you can switch to vi mode with the following command:

```
$ set -o vi
```

emacs mode

The next command switches back to emacs mode:

```
$ set -o emacs
```
vi Editing Mode

Before you start make sure you are in vi mode.

When you enter bash commands while in vi editing mode, you are in Input mode (page 142). As you enter a command, if you discover an error before you press RETURN, you can press ESCAPE to switch to vi Command mode. This setup is different from the stand-alone vi(m) editor's initial mode. While in Command mode you can use many vi(m) commands to edit the command line. It is as though you were using vi(m) to edit a copy of the history file with a screen that has room for only one command. When you use the k command or the UP ARROW to move up a line, you access the previous command. If you then use the j command or the DOWN ARROW to move down a line, you will return to the original command. To use the k and j keys to move between commands you must be in Command mode; you can use the ARROW keys in both Command and Input modes.

tip: The stand-alone editor starts in Command mode

The stand-alone vim editor starts in Command mode, whereas the command line vi(m) editor starts in Input mode. If commands display characters and do not work properly, you are in Input mode. Press ESCAPE and enter the command again.

In addition to cursor-positioning commands, you can use the search-backward (?) command followed by a search string to look back through your history list for the most recent command containing that string. If you have moved back in your history list, use a forward slash (/) to search forward toward your most recent command. Unlike the search strings in the stand-alone vi(m) editor, these search strings cannot contain regular expressions. You can, however, start the search string with a caret (^) to force the shell to locate commands that start with the search string. As in vi(m), pressing n after a successful search looks for the next occurrence of the same string.

You can also access events in the history list by using event numbers. While you are in Command mode (press ESCAPE), enter the event number followed by a G to go to the command with that event number.

When you use /, ?, or G to move to a command line, you are in Command mode, not Input mode. Now you can edit the command as you like or press RETURN to execute it.

Once the command you want to edit is displayed, you can modify the command line using vi(m) Command mode editing commands such as x (delete character), r (replace character), ~ (change case), and . (repeat last change). To change to Input mode, use an Insert (i, I), Append (a, A), Replace (R), or Change (c, C) command. You do not have to return to Command mode to run a command; simply press RETURN, even if the cursor is in the middle of the command line.

Refer to page 188 for a summary of vim commands.

emacs Editing Mode

Unlike the vi(m) editor, emacs is modeless. You need not switch between Command mode and Input mode because most emacs commands are control characters (page 204), allowing emacs to distinguish between input and commands. Like vi(m), the emacs command line editor provides commands for moving the cursor on the command line and through the command history list and for modifying part or all of a command. The emacs command line editor commands differ in a few cases from the commands in the stand-alone emacs editor.

In emacs you perform cursor movement by using both CONTROL and ESCAPE commands. To move the cursor one character backward on the command line, press CONTROL-B. Press CONTROL-F to move one character forward. As in vi, you may precede these movements with counts. To use a count you must first press ESCAPE;
otherwise, the numbers you type will appear on the command line.

Like \texttt{vi(m)}, \texttt{emacs} provides word and line movement commands. To move backward or forward one word on the command line, press \texttt{ESCAPE b} or \texttt{ESCAPE f}. To move several words by using a count, press \texttt{ESCAPE} followed by the number and the appropriate escape sequence. To get to the beginning of the line, press \texttt{CONTROL-A}; to the end of the line, press \texttt{CONTROL-E}; and to the next instance of the character \texttt{c}, press \texttt{CONTROL-X CONTROL-F} followed by \texttt{c}.

You can add text to the command line by moving the cursor to the correct place and typing the desired text. To delete text, move the cursor just to the right of the characters that you want to delete and press the erase key (page 26) once for each character you want to delete.

\textbf{tip: CONTROL-D can terminate your screen session}

If you want to delete the character directly under the cursor, press \texttt{CONTROL-D}. If you enter \texttt{CONTROL-D} at the beginning of the line, it may terminate your shell session.

If you want to delete the entire command line, type the line kill character (page 27). You can type this character while the cursor is anywhere in the command line. If you want to delete from the cursor to the end of the line, use \texttt{CONTROL-K}.

Refer to page 241 for a summary of \texttt{emacs} commands.

\textbf{Readline Completion Commands}

You can use the \texttt{TAB} key to complete words you are entering on the command line. This facility, called completion, works in both \texttt{vi} and \texttt{emacs} editing modes and is similar to the completion facility available in \texttt{tcsh}. Several types of completion are possible, and which one you use depends on which part of a command line you are typing when you press \texttt{TAB}.

\textbf{Command Completion}

If you are typing the name of a command (the first word on the command line), pressing \texttt{TAB} results in \textit{command completion}. That is, \texttt{bash} looks for a command whose name starts with the part of the word you have typed. If no command starts with what you have entered, \texttt{bash} beeps. If there is one such command, \texttt{bash} completes the command name for you. If there is more than one choice, \texttt{bash} does nothing in \texttt{vi} mode and beeps in \texttt{emacs} mode. Pressing \texttt{TAB} a second time causes \texttt{bash} to display a list of commands whose names start with the prefix you typed and allows you to finish typing the command name.

In the following example, the user types \texttt{bz} and presses \texttt{TAB}. The shell beeps (the user is in \texttt{emacs} mode) to indicate that several commands start with the letters \texttt{bz}. The user enters another \texttt{TAB} to cause the shell to display a list of commands that start with \texttt{bz} followed by the command line as the user had entered it so far:

\begin{verbatim}
$ bz
   TAB
  (beep)
   TAB
\end{verbatim}
Next the user types `c` and presses TAB twice. The shell displays the two commands that start with `bzc`. The user types `a` followed by TAB and the shell then completes the command because only one command starts with `bzca`.

```
$ bz
  TAB (beep) TAB
bzcat  bzcmp

$ bzca
  TAB t
```

Pathname Completion

*Pathname completion*, which also uses TABs, allows you to type a portion of a pathname and have `bash` supply the rest. If the portion of the pathname that you have typed is sufficient to determine a unique pathname, `bash` displays that pathname. If more than one pathname would match it, `bash` completes the pathname up to the point where there are choices so that you can type more.

When you are entering a pathname, including a simple filename, and press TAB, the shell beeps (if the shell is in `emacs` mode, `vi` mode there is no beep). It then extends the command line as far as it can.

```
$ cat films/dar
  TAB (beep) cat films/dark_
```

In the `films` directory every file that starts with `dar` has `k_` as the next characters, so `bash` cannot extend the line further without making a choice among files. You are left with the cursor just past the `_` character. At this point you can continue typing the pathname or press TAB twice. In the latter case `bash` beeps, displays your choices, redisplays the command line, and again leaves the cursor just after the `_` character.
When you add enough information to distinguish between the two possible files and press TAB, **bash** displays the unique pathname. If you enter `p` followed by TAB after the `_` character, the shell completes the command line:

```bash
$ cat films/dark_ 
  ➔  
  TAB 
  (beep) 
  ➔  
  TAB 

dark_passage  dark_victory

$ cat films/dark_ 
```

Because there is no further ambiguity, the shell appends a SPACE so you can finish typing the command line or just press RETURN to execute the command. If the complete pathname is that of a directory, **bash** appends a slash (`/`) in place of a SPACE.

### Variable Completion

When typing a variable name, pressing TAB results in **variable completion**, where **bash** tries to complete the name of the variable. In case of an ambiguity, pressing TAB twice displays a list of choices:

```bash
$ echo $HO  
  ➔  
  TAB  
  ➔  
  TAB  

$HOME      $HOSTNAME  $HOSTTYPE

$ echo $HOM  
  ➔  
  TAB  
  ➔  
  E
```

**caution:** Pressing **RETURN** executes the command

Pressing RETURN causes the shell to execute the command regardless of where the cursor is on the command line.
The Bourne Again Shell and other programs that use the Readline Library read the file specified by the `INPUTRC` environment variable to obtain initialization information. If `INPUTRC` is not set, these programs read the `~/.inputrc` file. They ignore lines of `.inputrc` that are blank or that start with a pound sign (`#`).

### Variables

You can set variables in `.inputrc` to control the behavior of the Readline Library using the following syntax:

```
set variable value
```

Table 8-11 lists some variables and values you can use. See Readline Variables in the bash man or info page for a complete list.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>editing-mode</td>
<td>Set to <code>vi</code> to start Readline in <code>vi</code> mode. Set to <code>emacs</code> to start Readline in <code>emacs</code> mode (the default). Similar to the <code>set vi</code> and <code>set emacs</code> shell commands (page 305).</td>
</tr>
<tr>
<td>horizontal-scroll-mode</td>
<td>Set to <code>on</code> to cause long lines to extend off the right edge of the display area. Moving the cursor to the right when it is at the right edge of the display area shifts the line to the left so you can see more of the line. You can shift the line back by moving the cursor back past the left edge. The default value is <code>off</code>, which causes long lines to wrap onto multiple lines of the display.</td>
</tr>
<tr>
<td>mark-directories</td>
<td>Set to <code>off</code> to cause Readline not to place a slash (<code>/</code>) at the end of directory names it completes. Normally it is <code>on</code>.</td>
</tr>
<tr>
<td>mark-modified-lines</td>
<td>Set to <code>on</code> to cause Readline to precede modified history lines with an asterisk. The default value is <code>off</code>.</td>
</tr>
</tbody>
</table>

### Key Bindings

You can specify bindings that map keystroke sequences to Readline commands, allowing you to change or extend the default bindings. As in `emacs`, the Readline Library includes many commands that are not bound to a keystroke sequence. To use an unbound command, you must map it using one of the following forms:

```
keyname: command_name
"keystroke_sequence": command_name
```

In the first form, you spell out the name for a single key. For example, CONTROL-U would be written as `control-u`. This form is useful for binding commands to single keys.

In the second form, you specify a string that describes a sequence of keys that will be bound to the command. You can use the `emacs`-style backslash escape sequences to represent the special keys CONTROL (\C), META (\M), and ESCAPE (\e). Specify a backslash by escaping it with another backslash: `\`. Similarly, a double or single
and ESCAPE (\e). Specify a backslash by escaping it with another backslash: \\.
Similarly, a double or single quotation mark can be escaped with a backslash: " or '.

The **kill-whole-line** command, available in **emacs** mode only, deletes the current line. Put the following command in **.inputrc** to bind the **kill-whole-line** command (which is unbound by default) to the keystroke sequence **CONTROL-R**.

```plaintext
control-r: kill-whole-line
```

**bind**

Give the command **bind** `\P` to display a list of all Readline commands. If a command is bound to a key sequence, that sequence is shown. Commands you can use in **vi** mode start with **vi**. For example, **vi-next-word** and **vi-prev-word** move the cursor to the beginning of the next and previous words, respectively. Commands that do not begin with **vi** are generally available in **emacs** mode.

Use **bind** `\q` to determine which key sequence is bound to a command:

```plaintext
$ bind -q kill-whole-line
```

*kill-whole-line* can be invoked via "\C-r".

You can also bind text by enclosing it within double quotation marks (**emacs** mode only):

"QQ": "The Linux Operating System"

This command causes **bash** to insert the string **The Linux Operating System** when you type **QQ**.

**Conditional Constructs**

You can conditionally select parts of the **.inputrc** file using the **Sif** directive. The syntax of the conditional construct is

```plaintext
$if [ test 
[= value ]]
commands
[elseif
commands
$endif
```

where **test** is **mode**, **term**, or **bash**. If **test** equals **value** or if **test** is **true**, this structure executes the first set of **commands**. If **test** does not equal **value** or if **test** is **false**, it executes the second set of **commands** if they are present...
or exits from the structure if they are not present.

The power of the $if directive lies in the three types of tests it can perform.

1. You can test to see which mode is currently set.

   $if mode=vi

   The preceding test is true if the current Readline mode is vi and false otherwise. You can test for vi or emacs.

2. You can test the type of terminal.

   $if term=xterm

   The preceding test is true if the TERM variable is set to xterm. You can test for any value of TERM.

3. You can test the application name.

   $if bash

   The preceding test is true when you are running bash and not another program that uses the Readline Library. You can test for any application name.

These tests can customize the Readline Library based on the current mode, the type of terminal, and the application you are using. They give you a great deal of power and flexibility when using the Readline Library with bash and other programs.

The following commands in .inputrc cause CONTROL-Y to move the cursor to the beginning of the next word regardless of whether bash is in vi or emacs mode:

$ cat ~/.inputrc

set editing-mode vi

$if mode=vi

   "\C-y": vi-next-word

$else

   "\C-y": forward-word
Because `bash` reads the preceding conditional construct when it is started, you must set the editing mode in `.inputrc`. Changing modes interactively using `set` will not change the binding of CONTROL-Y.

For more information on the Readline Library, open the `bash man` page and give the command `/^READLINE`, which searches for the word `READLINE` at the beginning of a line.

**tip: If Readline commands do not work, log out and log in again**

The Bourne Again Shell reads `~/.inputrc` when you log in. After you make changes to this file, you should log out and log in again before testing the changes.
Aliases

An alias is a (usually short) name that the shell translates into another (usually longer) name or (complex) command. Aliases allow you to define new commands by substituting a string for the first token of a simple command. They are typically placed in the ~/.bashrc (bash) or ~/.tcshrc (tcsh) startup files so that they are available to interactive subshells.

Under bash the syntax of the alias builtin is

```
alias [name [= value]]
```

Under tcsh the syntax is

```
alias [name [value]]
```

In the bash syntax there are no SPACEs around the equal sign. If value contains SPACEs or TABs, you must enclose value between quotation marks. Unlike aliases under tcsh, a bash alias does not accept an argument from the command line in value. Use a bash function (page 315) when you need to use an argument.

An alias does not replace itself, which avoids the possibility of infinite recursion in handling an alias such as the following:

```
$ alias ls='ls -F'
```

You can nest aliases. Aliases are disabled for noninteractive shells (that is, shell scripts). To see a list of the current aliases, give the command alias. To view the alias for a particular name, use alias followed by the name and nothing else. You can use the unalias builtin to remove an alias.

When you give an alias builtin without any arguments, the shell displays a list of all defined aliases:

```
$ alias
alias ll='ls -l'
alias l='ls -ltr'
alias ls='ls -F'
alias zap='rm -i'
```
Most Linux distributions define at least some aliases. Give an `alias` command to see which aliases are in effect. You can delete the aliases you do not want from the appropriate startup file.

**Single Versus Double Quotation Marks in Aliases**

The choice of single or double quotation marks is significant in the alias syntax when the alias includes variables. If you enclose `value` within double quotation marks, any variables that appear in `value` are expanded when the alias is created. If you enclose `value` within single quotation marks, variables are not expanded until the alias is used. The following example illustrates the difference.

The `PWD` keyword variable holds the pathname of the working directory. Alex creates two aliases while he is working in his home directory. Because he uses double quotation marks when he creates the `dirA` alias, the shell substitutes the value of the working directory when he creates this alias. The `alias dirA` command displays the `dirA` alias and shows that the substitution has already taken place:

```bash
$ echo $PWD
/home/alex

$ alias dirA="echo Working directory is $PWD"
$ alias dirA
alias dirA='echo Working directory is /home/alex'
```

When Alex creates the `dirB` alias, he uses single quotation marks, which prevent the shell from expanding the `PWD` variable. The `alias dirB` command shows that the `dirB` alias still holds the unexpanded `PWD` variable:

```bash
$ alias dirB='echo Working directory is $PWD'
$ alias dirB
alias dirB='echo Working directory is $PWD'
```

After creating the `dirA` and `dirB` aliases, Alex uses `cd` to make `cars` his working directory and gives each of the aliases as commands. The alias that he created with double quotation marks displays the name of the directory that he created the alias in as the working directory (which is wrong) and the `dirB` alias displays the proper name of the working directory:

```bash
$ cd cars
$ dirA
Working directory is /home/alex
$ dirB
Working directory is /home/alex/cars
```
**tip: How to prevent the shell from invoking an alias**

The shell checks only simple, unquoted commands to see if they are aliases. Commands given as relative or absolute pathnames and quoted commands are not checked. When you want to give a command that has an alias but do not want to use the alias, precede the command with a backslash, specify the command's absolute pathname, or give the command as `./command`.

**Examples of Aliases**

The following alias allows you to type `r` to repeat the previous command or `r abc` to repeat the last command line that began with `abc`:

```bash
$ alias r='fc -s'
```

If you use the command `ls -ltr` frequently, you can create an alias that substitutes `ls -ltr` when you give the command `l`:

```bash
$ alias l='ls -ltr'

$ l

total 41
-rw-r--r--  1 alex   group   30015 Mar  1 2004 flute.ps
-rw-r-----  1 alex   group    3089 Feb 11 2005 XTerm.ad
-rw-r--r--  1 alex   group     641 Apr  1 2005 fixtax.icn
-rw-r--r--  1 alex   group     484 Apr  9 2005 maptax.icn
drwxrwxr-x  2 alex   group    1024 Aug  9 17:41 Tiger
drwxrwxr-x  2 alex   group    1024 Sep 10 11:32 testdir
-rwxr-xr-x  1 alex   group     485 Oct 21 08:03 floor
drwxrwxr-x  2 alex   group    1024 Oct 27 20:19 Test_Emacs
```

Another common use of aliases is to protect yourself from mistakes. The following example substitutes the interactive version of the `rm` utility when you give the command `zap`:

```bash
$ alias zap='rm -i'
$ zap f*
```
The `i` option causes `rm` to ask you to verify each file that would be deleted, to help you avoid accidentally deleting the wrong file. You can also alias `rm` with the `rm i` command: `alias rm='rm i'`.

The aliases in the next example cause the shell to substitute `ls l` each time you give an `ll` command and `ls F` when you use `ls`:

```
$ alias ls='ls -F'
$ alias ll='ls -l'

$ ll

total 41

drwxrwxr-x  2 alex  group  1024 Oct 27 20:19 Test_Emacs/
drwxrwxr-x  2 alex  group  1024 Aug 9 17:41 Tiger/
-rw-r-----  1 alex  group  3089 Feb 11 2005 XTerm.ad
-rw-r--r--  1 alex  group   641 Apr 1 2005 fixtax.icn
-rw-r--r--  1 alex  group  30015 Mar 1 2004 flute.ps
-rwxr-xr-x  1 alex  group   485 Oct 21 08:03 floor*
-rw-r--r--  1 alex  group   484 Apr 9 2005 maptax.icn
drwxrwxr-x  2 alex  group  1024 Sep 10 11:32 testdir/
```

The `F` option causes `ls` to print a slash (`/`) at the end of directory names and an asterisk (`*`) at the end of the names of executable files. In this example, the string that replaces the alias `ll` (`ls l`) itself contains an alias (`ls`). When it replaces an alias with its value, the shell looks at the first word of the replacement string to see whether it is an alias. In the preceding example, the replacement string contains the alias `ls`, so a second substitution occurs to produce the final command `ls F l`. (To avoid a recursive plunge, the `ls` in the replacement text, although an alias, is not expanded a second time.)

When given a list of aliases without the `value` field, the `alias` builtin responds by displaying the value of each defined alias. The `alias` builtin reports an error if an alias has not been defined:

```
$ alias ll 1 ls zap wx

alias ll='ls -l'
```
alias l='ls -ltr'
alias ls='ls -F'
alias zap='rm -i'
bash: alias: wx: not found

You can avoid alias substitution by preceding the aliased command with a backslash (\):

$ \ls
Test_Emacs XTerm.ad flute.ps maptax.icn
Tiger fixtax.icn floor testdir

Because the replacement of an alias name with the alias value does not change the rest of the command line, any arguments are still received by the command that gets executed:

$ ll f*
-rw-r--r-- 1 alex group 641 Apr 1 2005 fixtax.icn
-rw-r--r-- 1 alex group 30015 Mar 1 2004 flute.ps
-rwxr-xr-x 1 alex group 485 Oct 21 08:03 floor*

You can remove an alias with the unalias builtin. When the zap alias is removed, it is no longer displayed with the alias builtin and its subsequent use results in an error message:

$ unalias zap
$ alias
alias ll='ls -l'
alias l='ls -ltr'
alias ls='ls -F'
$ zap maptax.icn
bash: zap: command not found
Functions

A shell function (tcsh does not have functions) is similar to a shell script in that it stores a series of commands for execution at a later time. However, because the shell stores a function in the computer's main memory (RAM) instead of in a file on the disk, the shell can access it more quickly than the shell can access a script. The shell also preprocesses (parses) a function so that it starts up more quickly than a script. Finally the shell executes a shell function in the same shell that called it. If you define too many functions, the overhead of starting a subshell (as when you run a script) can become unacceptable.

You can declare a shell function in the ~/.bash_profile startup file, in the script that uses it, or directly from the command line. You can remove functions with the unset builtin. The shell does not keep functions once you log out.

**tip: Removing variables and functions**

If you have a shell variable and a function with the same name, using unset removes the shell variable. If you then use unset again with the same name, it removes the function.

The syntax that declares a shell function is

```
[function]
function-name
()
{

commands
}
```

where the word function is optional, function-name is the name you use to call the function, and commands comprise the list of commands the function executes when you call it. The commands can be anything you would include in a shell script, including calls to other functions.

The first brace ({ }) can appear on the same line as the function name. Aliases and variables are expanded when a function is read, not when it is executed. You can use the break statement (page 459) within a function to terminate its execution.

Shell functions are useful as a shorthand as well as to define special commands. The following function starts a process named process in the background, with the output normally displayed by process being saved in .process.out:

```
start_process( ) {

process > .process.out 2>&1 &

}
```

The next example shows how to create a simple function that displays the date, a header, and a list of the people who are using the system. This function runs the same commands as the whoson script described on page 264. In this example the function is being entered from the keyboard. The greater-than (>) signs are secondary shell prompts (PS2); do not enter them.
$ function whoson ( )
  > {  
  >   date  
  >   echo "Users Currently Logged On"  
  >   who  
  > }  

$ whoson

Sun Aug 7 15:44:58 PDT 2005

Users Currently Logged On

hls console Aug 6 08:59 (:0)

alex pts/4 Aug 6 09:33 (0.0)

jenny pts/7 Aug 6 09:23 (bravo.example.com)

Functions in startup files

If you want to have the whoson function always be available without having to enter it each time you log in, put its definition in ~/.bash_profile. Then run .bash_profile, using the . (dot) command to put the changes into effect immediately:

$ cat ~/.bash_profile

export TERM=vt100

stty kill '^u'

whoson ( )

{

   date

   echo "Users Currently Logged On"

   who

}

$ . ~/.bash_profile

You can specify arguments when you call a function. Within the function these arguments are available as positional parameters (page 480). The following example shows the arg1 function entered from the keyboard.
$ arg1 ( ) {
>    echo "$1"
> }

$ arg1 first_arg
first_arg

See the function **switch ()** on page 259 for another example of a function. "**Functions**" on page 477 discusses the use of local and global variables within a function.
The following function allows you to export variables using `tcsh` syntax. The `env` builtin lists all environment variables and their values and verifies that `setenv` worked correctly:

```
$ cat .bash_profile
...
# setenv - keep tcsh users happy
function setenv()
{
    if [ $# -eq 2 ]
    then
        eval $1=$2
        export $1
    else
        echo "Usage: setenv NAME VALUE" 1>&2
    fi
}
$ . ~/.bash_profile
$ setenv TCL_LIBRARY /usr/local/lib/tcl
$ env | grep TCL_LIBRARY
TCL_LIBRARY=/usr/local/lib/tcl
```

The `$#` special parameter (page 480) takes on the value of the number of command line arguments. This function uses the `eval` builtin to force `bash` to scan the command `$1=$2` twice. Because `$1=$2` begins with a dollar sign ($), the shell treats the entire string as a single token as a command. With variable substitution performed, the command name becomes `TCL_LIBRARY=/usr/local/lib/tcl`, which results in an error. Using `eval`, a second scanning splits the string into the three desired tokens, and the correct assignment occurs.
Controlling bash Features and Options

This section explains how to control bash features and options using command line options and the set and shopt builtins.

Command Line Options

Two kinds of command line options are available: short and long. Short options consist of a hyphen followed by a letter; long options have two hyphens followed by multiple characters. Long options must appear before short options on a command line that calls bash. Table 8-12 lists some commonly used command line options.

Table 8-12. Command line options

<table>
<thead>
<tr>
<th>Option</th>
<th>Explanation</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>Help</td>
<td>Displays a usage message.</td>
<td>help</td>
</tr>
<tr>
<td>No edit</td>
<td>Prevents users from using the Readline Library (page 305) to edit command lines in an interactive shell.</td>
<td>noediting</td>
</tr>
<tr>
<td>No profile</td>
<td>Prevents reading these startup files (page 257): /etc/profile, ~/.bash_profile, ~/.bash_login, and ~/.profile.</td>
<td>noprofile</td>
</tr>
<tr>
<td>No rc</td>
<td>Prevents reading the ~/.bashrc startup file (page 258). This option is on by default if the shell is called as sh.</td>
<td>norc</td>
</tr>
<tr>
<td>POSIX</td>
<td>Runs bash in POSIX mode.</td>
<td>posix</td>
</tr>
<tr>
<td>Version</td>
<td>Displays bash version information and exits.</td>
<td>version</td>
</tr>
<tr>
<td>Login</td>
<td>Causes bash to run as though it were a login shell.</td>
<td>l (lowercase &quot;l&quot;)</td>
</tr>
<tr>
<td>shopt</td>
<td>Runs a shell with the opt shopt option (page 319). A O (uppercase &quot;O&quot;) sets the [±]O [opt ] option; +O unsets it.</td>
<td>±o</td>
</tr>
</tbody>
</table>

End of options

On the command line, signals the end of options. Subsequent tokens are treated as arguments even if they begin with a hyphen (\(\)).

Shell Features

You can control the behavior of the Bourne Again Shell by turning features on and off. Different features use different methods to turn features on and off. The set builtin controls one group of features, while the shopt builtin controls another group. You can also control many features from the command line you use to call bash.

tip: Features, options, variables?

To avoid confusing terminology, this book refers to the various shell behaviors that you can control as features. The bash info page refers to them as "options" and "values of variables controlling optional shell behavior."

set ± o: Turns Shell Features On and Off

The set builtin (there is a set builtin in tcsh, but it works differently), when used with the ±o or +o option, enables, disables, and lists certain bash features. For example, the following command turns on the noclobber feature (page 119):
$ set -o noclobber

You can turn this feature off (the default) by giving the command

$ set +o noclobber

The command set o without an option lists each of the features controlled by set followed by its state (on or off). The command set +o without an option lists the same features in a form that you can use as input to the shell. Table 8-13 lists bash features.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>Syntax</th>
<th>Alternate syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>allexp</td>
<td>Automatically exports all variables and functions that you create or modify after giving this command.</td>
<td>set o allexp</td>
<td>set a</td>
</tr>
<tr>
<td>braceexpand</td>
<td>Causes bash to perform brace expansion (the default; page 324).</td>
<td>set o braceexpand</td>
<td>set B</td>
</tr>
<tr>

<tr>
<td>xtrace</td>
<td>Turns on shell debugging (page 448).</td>
<td><code>set -o xtrace</code></td>
<td>set <code>-x</code></td>
</tr>
</tbody>
</table>

**shopt**: Turns Shell Features On and Off

The `shopt` (shell option) builtin (not available in `tcsh`) enables, disables, and lists certain `bash` features that control the behavior of the shell. For example, the following command causes `bash` to include filenames that begin with a period (.) when it expands ambiguous file references (the `-s` stands for `set`):

```
$ shopt -s dotglob
```

You can turn this feature off (the default) by giving the command (the `-u` stands for `unset`)

```
$ shopt -u dotglob
```

The shell displays how a feature is set if you give the name of the feature as the only argument to `shopt`:

```
$ shopt dotglob

dotglob      off
```
The command `shopt` without any options or arguments lists the features controlled by `shopt` and their state. The command `shopt` without an argument lists the features controlled by `shopt` that are set or on. The command `shopt u` lists the features that are unset or off. Table 8-13 lists bash features.

**Tip: Setting set ±o features using shopt**

You can use `shopt` to set/unset features that are otherwise controlled by `set ±o`. Use the regular `shopt` syntax with `-s` or `-u` and include the `-o` option. For example, the following command turns on the `noclobber` feature:

```
$ shopt -o -s noclobber
```
Processing The Command Line

Whether you are working interactively or running a shell script, `bash` needs to read a command line before it can start processing it. `bash` always reads at least one line before processing a command. Some `bash` builtins, such as `if` and `case`, as well as functions and quoted strings, span multiple lines. When `bash` recognizes a command that covers more than one line, it reads the entire command before processing it. In interactive sessions `bash` prompts you with the secondary prompt (`PS2`, `>` by default; page 287) as you type each line of a multiline command until it recognizes the end of the command:

```
$ echo 'hi
> end'
hi
end

$ function hello () {
> echo hello there
> }
$
```

After reading a command line, `bash` applies history expansion and alias substitution to the line.

History Expansion

"Reexecuting and Editing Commands" on page 297 discusses the commands you can give to modify and reexecute command lines from the history list. History expansion is the process that `bash` uses to turn a history command into an executable command line. For example, when you give the command `!!`, history expansion changes that command line so it is the same as the previous one. History expansion is turned on by default for interactive shells; `set +o histexpand` turns it off. History expansion does not apply to noninteractive shells (shell scripts).

Alias Substitution

Aliases (page 312) substitute a string for the first word of a simple command. By default aliases are turned on for interactive shells and off for noninteractive shells. Give the command `shopt u expand_aliases` to turn aliases off.

Parsing and Scanning the Command Line

After processing history commands and aliases, `bash` does not execute the command immediately. One of the first things the shell does is to parse (isolate strings of characters in) the command line into tokens or words. The shell then scans each token for special characters and patterns that instruct the shell to take certain actions. These actions can involve substituting one word or words for another. When the shell parses the following command line, it breaks it into three tokens (`cp`, `~/letter`, and `.`):
$ cp ~/letter .

After separating tokens and before executing the command, the shell scans the tokens and performs command line expansion.

Command Line Expansion

In both interactive and noninteractive use, the shell transforms the command line using command line expansion before passing the command line to the program being called. You can use a shell without knowing much about command line expansion, but you can use what a shell has to offer to a better advantage with an understanding of this topic. This section covers Bourne Again Shell command line expansion; TC Shell command line expansion is covered starting on page 344.

The Bourne Again Shell scans each token for the various types of expansion and substitution in the following order. Most of these processes expand a word into a single word. Only brace expansion, word splitting, and pathname expansion can change the number of words in a command (except for the expansion of the variable "$@" on page 482).

1. Brace expansion (page 324)
2. Tilde expansion (page 326)
3. Parameter and variable expansion (page 326)
4. Arithmetic expansion (page 327)
5. Command substitution (page 329)
6. Word splitting (page 330)
7. Pathname expansion (page 330)
8. Process substitution (page 332)

Quote removal

After bash finishes with the preceding list, it removes from the command line single quotation marks, double quotation marks, and backslashes that are not a result of an expansion. This process is called quote removal.

Order of Expansion

The order in which bash carries out these steps affects the interpretation of commands. For example, if you set a variable to a value that looks like the instruction for output redirection and then enter a command that uses the variable's value to perform redirection, you might expect bash to redirect the output.

$ SENDIT="> /tmp/saveit"

$ echo xxx $SENDIT
In fact, the shell does not redirect the output; it recognizes input and output redirection before it evaluates variables. When it executes the command line, the shell checks for redirection and, finding none, evaluates the SENDIT variable. After replacing the variable with > /tmp/saveit, bash passes the arguments to echo, which dutifully copies its arguments to standard output. No /tmp/saveit file is created.

The following sections provide more detailed descriptions of the steps involved in command processing. Keep in mind that double and single quotation marks cause the shell to behave differently when performing expansions. Double quotation marks permit parameter and variable expansion but suppress other types of expansion. Single quotation marks suppress all types of expansion.

Brace Expansion

Brace expansion, which originated in the C Shell, provides a convenient way to specify filenames when pathname expansion does not apply. Although brace expansion is almost always used to specify filenames, the mechanism can be used to generate arbitrary strings; the shell does not attempt to match the brace notation with the names of existing files.

Brace expansion is turned on in interactive and noninteractive shells by default; you can turn it off with set +o braceexpand. The shell also uses braces to isolate variable names (page 280).

The following example illustrates how brace expansion works. The ls command does not display any output because there are no files in the working directory. The echo builtin displays the strings that the shell generates with brace expansion. In this case the strings do not match filenames (there are no files in the working directory.)

$ ls
$ echo chap_{one,two,three}.txt
chap_one.txt chap_two.txt chap_three.txt

The shell expands the comma-separated strings inside the braces in the echo command into a SPACE-separated list of strings. Each string from the list is prepended with the string chap_, called the preamble, and appended with the string .txt, called the postscript. Both the preamble and the postscript are optional. The left-to-right order of the strings within the braces is preserved in the expansion. For the shell to treat the left and right braces specially and for brace expansion to occur, at least one comma and no unquoted whitespace characters must be inside the braces. You can nest brace expansions.

Brace expansion is useful when there is a long preamble or postscript. The following example copies the four files main.c, f1.c, f2.c, and tmp.c located in the /usr/local/src/C directory to the working directory:

$ cp /usr/local/src/C/{main,f1,f2,tmp}.c .
You can also use brace expansion to create directories with related names:

```bash
$ ls -F
file1  file2  file3
$ mkdir vrs{A,B,C,D,E}
$ ls -F
file1  file2  file3  vrsA/  vrsB/  vrsC/  vrsD/  vrsE/
```

The `-F` option causes `ls` to display a slash (`/`) after a directory and an asterisk (`*`) after an executable file.

If you tried to use an ambiguous file reference instead of braces to specify the directories, the result would be different (and not what you wanted):

```bash
$ rmdir vrs*
$ mkdir vrs[A-E]
$ ls -F
file1  file2  file3  vrs[A-E]/
```

An ambiguous file reference matches the names of existing files. Because it found no filenames matching `vrs[A-E]`, `bash` passed the ambiguous file reference to `mkdir`, which created a directory with that name. Page 130 has a discussion of brackets in ambiguous file references.

**Tilde Expansion**

Chapter 4 (page 89) showed a shorthand notation to specify your home directory or the home directory of another user. This section provides a more detailed explanation of tilde expansion.

The tilde (`~`) is a special character when it appears at the start of a token on a command line. When it sees a tilde in this position, `bash` looks at the following string of characters up to the first slash (`/`) or to the end of the word if there is no slash; as a possible login name. If this possible login name is null (that is, if the tilde appears as a word by itself or if it is immediately followed by a slash), the shell substitutes the value of the `HOME` variable for the tilde. The following example demonstrates this expansion, where the last command copies the file named `letter` from Alex's home directory to the working directory:

```bash
$ echo $HOME
/home/alex
```
$ echo ~
/home/alex

$ echo ~/letter
/home/alex/letter

$ cp ~/letter .

If the string of characters following the tilde forms a valid login name, the shell substitutes the path of the home
directory associated with that login name for the tilde and name. If it is not null and not a valid login name, the shell
does not make any substitution:

$ echo ~jenny
/home/jenny

$ echo ~root
/root

$ echo ~xx
~xx

Tildes are also used in directory stack manipulation (page 274). In addition, ~ + is a synonym for PWD (the name
of the working directory), and ~ ņ is a synonym for OLDPWD (the name of the previous working directory).

Parameter and Variable Expansion

On a command line a dollar sign ($) that is not followed by an open parenthesis introduces parameter or variable
expansion. Parameters include command line, or positional, parameters (page 480) and special parameters (page
478). Variables include user-created variables (page 278) and keyword variables (page 283). The bash man and
info pages do not make this distinction, however.

Parameters and variables are not expanded if they are enclosed within single quotation marks or if the leading dollar
sign is escaped (preceded with a backslash). If they are enclosed within double quotation marks, the shell expands
parameters and variables.

Arithmetic Expansion

The shell performs arithmetic expansion by evaluating an arithmetic expression and replacing it with the result. See
page 358 for information on arithmetic expansion under tcsh. Under bash the syntax for arithmetic expansion is

```
$((
  expression
))
```
The shell evaluates expression and replaces $(( expression )) with the result of the evaluation. This syntax is similar to the syntax used for command substitution [$(...)] and performs a parallel function. You can use $(( expression )) as an argument to a command or in place of any numeric value on a command line.

The rules for forming expression are the same as those found in the C programming language; all standard C arithmetic operators are available (see Table 11-8 on page 505). Arithmetic in bash is done using integers. Unless you use variables of type integer (page 283) or actual integers, however, the shell must convert string-valued variables to integers for the purpose of the arithmetic evaluation.

You do not need to precede variable names within expression with a dollar sign ($). In the following example, an arithmetic expression determines how many years are left until age 60:

```bash
$ cat age_check
#!bin/bash

echo -n "How old are you? "
read age

echo "Wow, in $((60-age)) years, you'll be 60!"
```

You do not need to enclose the expression within quotation marks because bash does not perform filename expansion on it. This feature makes it easier for you to use an asterisk (*) for multiplication, as the following example shows:

```bash
$ echo There are $((60*60*24*365)) seconds in a non-leap year.
There are 31536000 seconds in a non-leap year.
```

The next example uses wc, cut, arithmetic expansion, and command substitution to estimate the number of pages required to print the contents of the file letter.txt. The output of the wc utility (page 816) used with the l option is the number of lines in the file, in columns 1 through 4, followed by a SPACE and the name of the file (the first command following). The cut utility (page 627) with the c1-4 option extracts the first four columns.

**tip: Fewer dollar signs ($)**

When you use variables within $(( and )), the dollar signs that precede individual variable references are optional:
$ x=23 \ y=37
$ echo $(2*$x + 3*$y))
157
$ echo $((2*x + 3*y))
157

$ wc -l letter.txt
351 letter.txt
$ wc -l letter.txt | cut -c1-4
351

The dollar sign and single parenthesis instruct the shell to perform command substitution; the dollar sign and double parentheses indicate arithmetic expansion:

$ echo $(( $(wc -l letter.txt | cut -c1-4)/66 + 1))
6

The preceding example sends standard output from wc to standard input of cut via a pipe. Because of command substitution, the output of both commands replaces the commands between the $( and the matching ) on the command line. Arithmetic expansion then divides this number by 66, the number of lines on a page. A 1 is added at the end because the integer division results in any remainder being discarded.

Another way to get the same result without using cut is to redirect the input to wc instead of having wc get its input from a file you name on the command line. When you redirect its input, wc does not display the name of the file:

$ wc -l < letter.txt
351

It is common practice to assign the result of arithmetic expansion to a variable:

$ numpages=$( $(wc -l < letter.txt)/66 + 1))
The `let` builtin (not available in `tcsh`) evaluates arithmetic expressions just as the `$()` syntax does. The following command is equivalent to the preceding one:

```bash
$ let "numpages=$(wc -l < letter.txt)/66 + 1"
```

The double quotation marks keep the SPACES (both those you can see and those that result from the command substitution) from separating the expression into separate arguments to `let`. The value of the last expression determines the exit status of `let`. If the value of the last expression is 0, the exit status of `let` is 1; otherwise, the exit status is 0.

You can give multiple arguments to `let` on a single command line:

```bash
$ let a=5+3 b=7+2
$ echo $a $b
8 9
```

When you refer to variables when doing arithmetic expansion with `let` or `$()`, the shell does not require you to begin the variable name with a dollar sign ($). Nevertheless, it is a good practice to do so, as in most places you must include this symbol.

**Command Substitution**

`Command substitution` replaces a command with the output of that command. The preferred syntax for command substitution under `bash` follows:

```bash
$(command)
```

Under `bash` you can also use the following syntax, which is the only syntax allowed under `tcsh`:

```
command
```

The shell executes `command` within a subshell and replaces `command`, along with the surrounding punctuation, with standard output of `command`.

In the following example, the shell executes `pwd` and substitutes the output of the command for the command and surrounding punctuation. Then the shell passes the output of the command, which is now an argument, to `echo`, which displays it.
$ echo $(pwd)
/home/alex

The next script assigns the output of the `pwd` builtin to the variable `where` and displays a message containing the value of this variable:

$ cat where

where=$(pwd)

echo "You are using the $where directory."

$ where

You are using the /home/jenny directory.

Although it illustrates how to assign the output of a command to a variable, this example is not realistic. You can more directly display the output of `pwd` without using a variable:

$ cat where2

echo "You are using the $(pwd) directory."

$ where2

You are using the /home/jenny directory.

The following command uses `find` to locate files with the name `README` in the directory tree with its root at the working directory. This list of files is standard output of `find` and becomes the list of arguments to `ls`.

$ ls -l $(find . -name README -print)

The next command line shows the older `'command'` syntax:

$ ls -l 'find . -name README -print'

One advantage of the newer syntax is that it avoids the rather arcane rules for token handling, quotation mark handling, and escaped back ticks within the old syntax. Another advantage of the new syntax is that it can be nested, unlike the old syntax. For example, you can produce a long listing of all `README` files whose size exceeds the size of `./README` with the following command:
$ ls -l $(find . -name README -size +$(echo $(cat ./README | wc -c)c ) -print

Try giving this command after giving a `set` command (page 448) to see how `bash` expands it. If there is no README file, you just get the output of `ls -l`.

For additional scripts that use command substitution, see pages 444, 464, and 496.

```
tip: $( Versus $(

The symbols $( constitute a separate token. They introduce an arithmetic expression, not a command substitution. Thus, if you want to use a parenthesized subshell (page 270) within $( ), you must insert a SPACE between the $( and the next (.
```

Word Splitting

The results of parameter and variable expansion, command substitution, and arithmetic expansion are candidates for word splitting. Using each character of `IFS` (page 288) as a possible delimiter, `bash` splits these candidates into words or tokens. If `IFS` is unset, `bash` uses its default value (SPACE-TAB-NEWLINE). If `IFS` is null, `bash` does not split words.

Pathname Expansion

Pathname expansion (page 127), also called filename generation or globbing, is the process of interpreting ambiguous file references and substituting the appropriate list of filenames. Unless `noglob` (page 321) is set, the shell performs this function when it encounters an ambiguous file reference a token containing any of the unquoted characters *, ?, [ or ] . If `bash` cannot locate any files that match the specified pattern, the token with the ambiguous file reference is left alone. The shell does not delete the token or replace it with a null string but rather passes it to the program as is (except see `nullglob`, page 322). The TC Shell generates an error message.

In the first `echo` command in the following example, the shell expands the ambiguous file reference `tmp *` and passes three tokens (`tmp1`, `tmp2`, and `tmp3`) to `echo`. The `echo` builtin displays the three filenames it was passed by the shell. After `rm` removes the three `tmp *` files, the shell finds no filenames that match `tmp *` when it tries to expand it. Thus it passes the unexpanded string to the `echo` builtin, which displays the string it was passed.

```
$ ls
 tmp1 tmp2 tmp3
$ echo tmp*
 tmp1 tmp2 tmp3
$ rm tmp*
$ echo tmp*
 tmp*
```
By default the same command causes the TC Shell to display an error message:

```bash
tcsh $ echo tmp*
```

```
echo: No match
```

A period that either starts a pathname or follows a slash (/) in a pathname must be matched explicitly unless you have set `dotglob` (page 320). The option `nocaseglob` (page 321) causes ambiguous file references to match filenames without regard to case.

### Quotation marks

Putting double quotation marks around an argument causes the shell to suppress pathname and all other expansion except parameter and variable expansion. Putting single quotation marks around an argument suppresses all types of expansion. The second `echo` command in the following example shows the variable `Salex` between double quotation marks, which allow variable expansion. As a result the shell expands the variable to its value: `sonar`. This expansion does not occur in the third `echo` command, which uses single quotation marks. Because neither single nor double quotation marks allow pathname expansion, the last two commands display the unexpanded argument `tmp *`.

```bash
$ echo tmp* $alex
tmp1 tmp2 tmp3 sonar

$ echo "tmp* $alex"
tmp* sonar

$ echo 'tmp* $alex'
tmp* $alex
```

The shell distinguishes between the value of a variable and a reference to the variable and does not expand ambiguous file references if they occur in the value of a variable. As a consequence you can assign to a variable a value that includes special characters, such as an asterisk (`*`).

### Levels of expansion

In the next example, the working directory has three files whose names begin with `letter`. When you assign the value `letter *` to the variable `var`, the shell does not expand the ambiguous file reference because it occurs in the value of a variable (in the assignment statement for the variable). No quotation marks surround the string `letter *`; context alone prevents the expansion. After the assignment the `set` builtin (with the help of `grep`) shows the value of `var` to be `letter *`.

The three `echo` commands demonstrate three levels of expansion. When `Svar` is quoted with single quotation marks, the shell performs no expansion and passes the character string `Svar` to `echo`, which displays it. When you use double quotation marks, the shell performs variable expansion only and substitutes the value of the `var` variable for
its name, preceded by a dollar sign. No pathname expansion is performed on this command because double quotation marks suppress it. In the final command, the shell, without the limitations of quotation marks, performs variable substitution and then pathname expansion before passing the arguments to `echo`.

```
$ ls letter*
letter1  letter2  letter3
$ var=letter*
$ set | grep var
var='letter*'
$ echo 'Svar'
$var
$ echo "$var"
letter*
$ echo $var
letter1 letter2 letter3
```

Process Substitution

A special feature of the Bourne Again Shell is the ability to replace filename arguments with processes. An argument with the syntax `<(command)` causes `command` to be executed and the output written to a named pipe (FIFO). The shell replaces that argument with the name of the pipe. If that argument is then used as the name of an input file during processing, the output of `command` is read. Similarly an argument with the syntax `>(command)` is replaced by the name of a pipe that `command` reads as standard input.

The following example uses `sort` (page 762) with the `-m` (merge, which works correctly only if the input files are already sorted) option to combine two word lists into a single list. Each word list is generated by a pipe that extracts words matching a pattern from a file and sorts the words in that list.

```
$ sort -m -f <(grep "^[A-Z].*$" memo1 | sort) <(grep ".*aba.*" memo2 |sort)
```
Chapter Summary

The shell is both a command interpreter and a programming language. As a command interpreter, the shell executes commands you enter in response to its prompt. As a programming language, the shell executes commands from files called shell scripts. When you start a shell, it typically runs one or more startup files.

Running a shell script

Assuming that the file holding a shell script is in the working directory, there are three basic ways to execute the shell script from the command line.

1. Type the simple filename of the file that holds the script.
2. Type a relative pathname, including the simple filename preceded by ./.
3. Type `bash` or `tcsh` followed by the name of the file.

Technique 1 requires that the working directory be in the `PATH` variable. Techniques 1 and 2 require that you have execute and read permission for the file holding the script. Technique 3 requires that you have read permission for the file holding the script.

Job control

A job is one or more commands connected by pipes. You can bring a job running in the background into the foreground by using the `fg` builtin. You can put a foreground job into the background by using the `bg` builtin, provided that you first suspend the job by pressing the suspend key (typically CONTROL-Z). Use the `jobs` builtin to see which jobs are running or suspended.

Variables

The shell allows you to define variables. You can declare and initialize a variable by assigning a value to it; you can remove a variable declaration by using `unset`. Variables are local to a process unless they are exported using the `export` (bash) or `setenv` (tcsh) builtin to make them available to child processes. Variables you declare are called `user-created` variables. The shell also defines called `keyword` variables. Within a shell script you can work with the command line (`positional`) parameters the script was called with.

Process

Each process has a unique identification (PID) number and is the execution of a single Linux command. When you give it a command, the shell forks a new (child) process to execute the command, unless the command is built into the shell (page 132). While the child process is running, the shell is in a state called sleep. By ending a command line with an ampersand (&), you can run a child process in the background and bypass the sleep state so that the shell prompt returns immediately after you press RETURN. Each command in a shell script forks a separate process, each of which may in turn fork other processes. When a process terminates, it returns its exit status to its parent process. An exit status of zero signifies success and nonzero signifies failure.

History

The history mechanism, a feature adapted from the C Shell, maintains a list of recently issued command lines, also called `events`, that provides a way to reexecute previous commands quickly. There are several ways to work with the
called events, that provides a way to reexecute previous commands quickly. There are several ways to work with the history list; one of the easiest is to use a command line editor.

**Command line editors**

When using an interactive Bourne Again Shell, you can edit your command line and commands from the history file, using either of the Bourne Again Shell's command line editors (vi[m] or emacs). When you use the vi(m) command line editor, you start in Input mode, unlike the way you normally enter vi(m). You can switch between Command and Input modes. The emacs editor is modeless and distinguishes commands from editor input by recognizing control characters as commands.

**Aliases**

An alias is a name that the shell translates into another name or (complex) command. Aliases allow you to define new commands by substituting a string for the first token of a simple command. The Bourne Again and TC Shells use different syntaxes to define an alias, but aliases in both shells work similarly.

**Functions**

A shell function is a series of commands that, unlike a shell script, are parsed prior to being stored in memory so that they run faster than shell scripts. Shell scripts are parsed at runtime and are stored on disk. A function can be defined on the command line or within a shell script. If you want the function definition to remain in effect across login sessions, you can define it in a startup file. Like the functions of a programming language, a shell function is called by giving its name followed by any arguments.

**Shell features**

There are several ways to customize the shell's behavior. You can use options on the command line when you call bash and you can use the bash set and shopt builtins to turn features on and off.

**Command line expansion**

When it processes a command line, the Bourne Again Shell may replace some words with expanded text. Most types of command line expansion are invoked by the appearance of a special character within a word (for example, a leading dollar sign denotes a variable). See Table 8-6 on page 291 for a list of special characters. The expansions take place in a specific order. Following the history and alias expansions, the common expansions are parameter and variable expansion, command substitution, and pathname expansion. Surrounding a word with double quotation marks suppresses all types of expansion except parameter and variable expansion. Single quotation marks suppress all types of expansion, as does quoting (escaping) a special character by preceding it with a backslash.
Exercises

1. Explain the following unexpected result:

   $ whereis date
   date: /bin/date

   $ echo $PATH
   .:/usr/local/bin:/usr/bin:/bin

   $ cat > date
   echo "This is my own version of date."

   $ date
   Tue May 24 11:45:49 PDT 2005

2. What are two ways you can execute a shell script when you do not have execute access permission for the file containing the script? Can you execute a shell script if you do not have read access permission for the file containing the script?

3. What is the purpose of the **PATH** variable?

   a. Set the **PATH** variable so that it causes the shell to search the following directories in order:

      - /usr/local/bin
      - /usr/bin/X11
      - /usr/bin
      - /bin
      - /usr/kerberos/bin
      - The **bin** directory in your home directory
      - The working directory

   b. If there is a file named **doit** in /usr/bin and another file with the same name in your ~/bin, which one will be executed? (Assume that you have execute permission for both files.)

   c. If your **PATH** variable is not set to search the working directory, how can you execute
a program located there?

d. Which command can you use to add the directory /usr/games to the end of the list of directories in PATH?

4. Assume that you have made the following assignment:

$ person=jenny

Give the output of each of the following commands:

a. echo $person

b. echo ' $person '

c. echo "$person"

5. The following shell script adds entries to a file named journal-file in your home directory. This script helps you keep track of phone conversations and meetings.

$ cat journal

# journal: add journal entries to the file
# $HOME/journal-file

file=$HOME/journal-file
date >> $file
echo -n "Enter name of person or group: 
read name
echo "$name" >> $file
echo >> $file
cat >> $file
echo "-----------------------------------------------" >> $file
echo >> $file
a. What do you have to do to the script to be able to execute it?

b. Why does the script use the read builtin (page 487) the first time it accepts input from the terminal and the cat utility the second time?

6. Assume that the /home/jenny/grants/biblios and /home/jenny/biblios directories exist. Give Jenny's working directory after she executes each sequence of commands given. Explain what happens in each case.

```
$ pwd
/home/jenny/grants
$ CDPATH=$(pwd)
$ cd
$ cd biblios

$ pwd
/home/jenny/grants
$ CDPATH=$(pwd)
$ cd $HOME/biblios
```

7. Name two ways you can identify the PID number of your login shell.

8. Give the following command:

```
$ sleep 30 | cat /etc/inittab
```

Is there any output from sleep? Where does cat get its input from? What has to happen before the shell displays another prompt?
Advanced Exercises

9. Write a sequence of commands or a script that demonstrates that variable expansion occurs before pathname expansion.

10. Write a shell script that outputs the name of the shell that is executing it.

11. Explain the behavior of the following shell script:

```bash
$ cat quote_demo
twoliner="This is line 1.
This is line 2."
echo "$twoliner"
echo $twoliner
```

a. How many arguments does each `echo` command see in this script? Explain.

b. Redefine the `IFS` shell variable so that the output of the second `echo` is the same as the first.

12. Add the exit status of the previous command to your prompt so that it behaves similarly to the following:

```bash
$ [0] ls xxx
ls: xxx: No such file or directory
$ [1]
```

13. The `dirname` utility treats its argument as a pathname and writes to standard output the path prefix—that is, everything up to but not including the last component:

```bash
$ dirname a/b/c/d
a/b/c
```

If you give `dirname` a simple filename (no `/` characters) as an argument, `dirname` writes a . to
standard output:

```
$ dirname simple
.
```

Implement `dirname` as a `bash` function. Make sure that it behaves sensibly when given such arguments as `/`.

14. Implement the `basename` utility, which writes the last component of its pathname argument to standard output, as a `bash` function. For example, given the pathname `a/b/c/d`, `basename` writes `d` to standard output:

```
$ basename a/b/c/d
```

15. The Linux `basename` utility has an optional second argument. If you give the command `basename path suffix`, `basename` removes the `suffix` and the prefix from `path`:

```
$ basename src/shellfiles/prog.bash .bash
prog
$ basename src/shellfiles/prog.bash .c
prog.bash
```

Add this feature to the function you wrote for exercise 14.
Chapter 9. The Tc Shell

IN THIS CHAPTER

Shell Scripts 340

Entering and Leaving the TC Shell 341

Features Common to the Bourne Again and TC Shells 343

Redirecting Standard Error 349

Word Completion 350

Editing the Command Line 353

Variables 355

Reading User Input 361

Control Structures 368

Builtins 377

The TC Shell (tcsh) performs the same function as the Bourne Again Shell and other shells: It provides an interface between you and the Linux operating system. The TC Shell is an interactive command interpreter as well as a high-level programming language. Although you use only one shell at any given time, you should be able to switch back and forth comfortably between shells as the need arises (you may want to run different shells in different windows). Chapters 8 and 11 apply to tcsh as well as to bash so they provide a good background for this chapter. This chapter explains tcsh features that are not found in bash and those that are implemented differently from their bash counterparts. The tcsh home page is www.tcsh.org.

The TC Shell is an expanded version of the C Shell (csh), which originated on Berkeley UNIX. The "T" in TC Shell comes from the TENEX and TOPS-20 operating systems, which inspired command completion and other features in the TC Shell. A number of features not found in csh are present in tcsh, including file and username completion, command line editing, and spelling correction. As with csh, you can customize tcsh to make it more tolerant of mistakes and easier to use. By setting the proper shell variables, you can have tcsh warn you when you appear to be accidentally logging out or overwriting a file. Many popular features of the original C Shell are now shared by bash and tcsh.
Assignment statement

Although some of the functionality of tcsh is present in bash, differences arise in the syntax of some commands. For example, the tcsh assignment statement has the following syntax:

```
set variable = value
```

Having spaces on either side of the equal sign, although illegal in bash, is allowed in tcsh. By convention shell variables in tcsh are generally named with lowercase letters, not uppercase (you can use either). If you reference an undeclared variable (one that has had no value assigned to it), tcsh will give you an error message, whereas bash will not. Finally the default tcsh prompt is a greater than sign (>), but it is frequently set to a single $ character followed by a SPACE. The examples in this chapter use a prompt of tcsh $ to avoid confusion with the bash prompt.

**tip: Do not use tcsh as a programming language**

If you have used UNIX and are comfortable with the C or TC Shell, you may want to use tcsh as your login shell. However, you may find that the TC Shell is not as good a programming language as bash. If you are going to learn only one shell programming language, learn bash. The Bourne Again Shell is used throughout Linux to program many system administration scripts.

Shell Scripts

With tcsh you can execute files containing TC Shell commands, just as bash can execute files containing Bourne Again Shell commands. The concepts of writing and executing scripts in the two shells are similar. However, the methods of declaring and assigning values to variables and the syntax of control structures are different.

You can run bash and tcsh scripts while using any one of the shells as a command interpreter. Various methods exist for selecting the shell that runs a script. Refer to "#! Specifies a Shell" on page 265 for more information.

If the first character of a shell script is a pound sign (#) and the following character is not an exclamation point (!), the TC Shell executes the script under tcsh. If the first character is anything other than #, tcsh calls the sh link to bash to execute the script.

**tip: echo: getting rid of the RETURN**

The tcsh echo builtin accepts either a \n option or a trailing \c to get rid of the RETURN that echo normally displays at the end of a line. The bash echo builtin accepts only the \n option (refer to "read: Accepts User Input" on page 487).

**tip: Shell game**

When you are working with an interactive TC Shell, if you run a script in which # is not the first character of the script and you call the script directly (without preceding its name with tcsh), tcsh calls the sh link to bash to run the script. The following script was written to be run under tcsh but, when called from a tcsh command line, is executed by bash. The set builtin (page 484) works differently under bash and tcsh. As a result the following example (from page 361) issues a prompt
but does not wait for you to respond:

```bash
tcsh $ cat user_in
echo -n "Enter input: "
set input_line = "$<"
echo $input_line

tcsh $ user_in
Enter input:
```

Although in each case the examples are run from a `tcsh` command line, the following one calls `tcsh` explicitly so that `tcsh` executes the script and it runs correctly.

```bash
tcsh $ tcsh user_in
Enter input: here is some input
here is some input
```

### Entering and Leaving the TC Shell

**chsh**

You can execute `tcsh` by giving the command `tcsh`. If you are not sure which shell you are using, use the `ps` utility to find out. It shows whether you are running `tcsh`, `bash`, `sh` (linked to `bash`), or possibly another shell. The `finger` command followed by your username displays the name of your login shell, which is stored in the `/etc/passwd` file. If you want to use `tcsh` as a matter of course, you can use the `chsh` (change shell) utility to change your login shell:

```bash
bash $ chsh
Changing shell for sam.
Password:
New shell [/bin/bash]: /bin/tcsh
Shell changed.
```
bash $

The shell you specify will be in effect for your next login and all subsequent logins until you specify a different login shell. The /etc/passwd file stores the name of your login shell.

You can leave tcsh in several ways. The approach you choose depends on two factors: whether the shell variable ignoreeof is set and whether you are using the shell that you logged in on (your login shell) or another shell that you created after you logged in. If you are not sure how to exit from tcsh, press CONTROL-D on a line by itself with no leading SPACEs, just as you would to terminate standard input to another program. You will either exit or receive instructions on how to exit. If you have not set ignoreeof (page 366) and it has not been set for you in a startup file, you can exit from any shell by using CONTROL-D (the same procedure you use to exit from the Bourne Again Shell).

When ignoreeof is set, CONTROL-D does not work. The ignoreeof variable causes the shell to display a message telling you how to exit. You can always exit from tcsh by giving an exit command. A logout command allows you to exit from your login shell only.

Startup Files

When you log in on the TC Shell, it automatically executes various startup files. These files are normally executed in the order described in this section, but you can compile tcsh so that it uses a different order. You must have read access to a startup file to execute the commands in it.

/etc/csh.cshrc and /etc/csh.login

The shell first executes the commands in /etc/csh.cshrc and /etc/csh.login. Superuser can set up these files to establish systemwide default characteristics for tcsh users. They contain systemwide configuration information, such as the default path, the location to check for mail, and so on.

.tcshrc and .cshrc

Next the shell looks for ~/.tcshrc or, if it does not exist, ~/.cshrc (~/ is shorthand for your home directory). You can use these files to establish variables and parameters that are local to your shell. Each time you create a new shell, tcsh reinitializes these variables for the new shell. The following .tcshrc file sets several shell variables, establishes two aliases (page 347), and adds two new directories to path—one at the start of the list and one at the end:

tcsh $ cat ~/.tcshrc

set noclobber
set dunique
set ignoreeof
set history=256
set path = (~/bin $path /usr/games)
alias h history
alias ll ls -l

.history

Login shells rebuild the history list from the contents of ~/.history. If the histfile variable exists, tcsh uses the file that histfile points to in place of .history.

.login

Login shells read and execute the commands in ~/.login. This file contains commands that you want to execute once, at the beginning of each session. You can use setenv (page 356) to declare environment (global) variables here. You can also declare the type of terminal you are using and set some terminal characteristics in your .login file.

tcsh $ cat ~/.login
setenv history 200
setenv mail /var/spool/mail/$user
if ( -z $DISPLAY ) then
    setenv TERM vt100
else
    setenv TERM xterm
endif
stty erase 'h' kill 'u' -lcase tab3
date '+Login on %A %B %d at %I:%M %p'

The preceding .login file establishes the type of terminal you are using by setting the TERM variable (the if statement [page 368] determines whether you are using a graphical interface and therefore what value should be assigned to TERM). It then runs stty (page 778) to set terminal characteristics and date (page 630) to display the time you logged in.

/etc/csh.logout and .logout

The TC Shell runs the /etc/csh.logout and ~/.logout files, in that order, when you exit from a login shell. The following sample .logout file uses date to display the time you logged out. The sleep command ensures that echo has time to display the message before the system logs you out. The delay may be useful for dial-up lines that
take some time to display the message.

tcsh $ cat ~/.logout
date '+Logout on %A %B %d at %I:%M %p'
sleep 5

Features Common to the Bourne Again and TC Shells

Most of the features common to both bash and tcsh are derived from the original C Shell:

- Command line expansion (also called substitution; page 344)
- History (page 344)
- Aliases (page 347)
- Job control (page 348)
- Filename substitution (page 348)
- Directory stack manipulation (page 349)
- Command substitution (page 349)

Because the chapters on bash discuss these features in detail, this section focuses on the differences between the bash and tcsh implementations.

Command Line Expansion (Substitution)

Refer to "Processing the Command Line" on page 322 for an introduction to command line expansion in the Bourne Again Shell. The tcsh man page uses the term substitution instead of expansion, which is used by bash. The TC Shell scans each token for possible expansion in the following order:

1. History substitution (page 344)
2. Alias substitution (page 347)
3. Variable substitution (page 356)
4. Command substitution (page 349)
5. Filename substitution (page 348)
6. Directory stack substitution (page 349)
The TC Shell assigns a sequential event number to each command line. You can display this event number as part of the tcsh prompt (refer to "prompt" on page 363). Examples in this section show numbered prompts when they help illustrate the behavior of a command.

**history Builtin**

As in bash, the tcsh history builtin displays the events in your history list. The list of events is ordered with the oldest events at the top. The last event in the history list is the history command that displayed the list. In the following history list, which is limited to ten lines by the argument of 10 to the history command, command 23 modifies the tcsh prompt to display the history event number. The time each command was executed appears to the right of the event number.

32 $ history 10

```plaintext
23  23:59   set prompt = "! $ "
24  23:59   ls -l
25  23:59   cat temp
26  0:00    rm temp
27  0:00    vim memo
28  0:00    lpr memo
29  0:00    vim memo
30  0:00    lpr memo
31  0:00    rm memo
32  0:00    history
```

**History Expansion**

The same event and word designators work in both shells. For example, !! refers to the previous event in tcsh, just as it does in bash. The command !328 executes event number 328 and !?txt? executes the most recent event containing the string txt. For more information refer to "Using an Exclamation Point (!) to Reference Events" on page 300. Table 9-1 lists the few tcsh word modifiers not found in bash.

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>u</td>
<td>Converts the first lowercase letter into uppercase</td>
</tr>
<tr>
<td>l</td>
<td>Converts the first uppercase letter into lowercase</td>
</tr>
<tr>
<td>a</td>
<td>Applies the next modifier globally within a single word</td>
</tr>
</tbody>
</table>
You can use more than one word modifier in a command. For instance, the `a` modifier, in combination with the `u` or `l` modifier, enables you to change the case of an entire word.

```bash
tcsh $ echo $VERSION

VERSION: Undefined variable.

tcsh $ echo !!:1:al
echo $version

tcsh 6.12.00 (Astron) 2002-07-23 (i386-intel-linux) options 8b,nls,...
```

In addition to using event designators to access the history list, you can use the command line editor to access, modify, and execute previous commands (page 353).

**Variables**

The variables that you set to control history in `tcsh` are different from those used in `bash`. Whereas `bash` uses `HISTSIZE` and `HISTFILESIZE` to determine the number of events that are preserved during and between sessions, `tcsh` uses `history` and `savehist` (Table 9-2) for these purposes.

### Table 9-2. History variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Default</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>history</td>
<td>100 events</td>
<td>Maximum number of events saved during a session</td>
</tr>
<tr>
<td>histfile</td>
<td>~/.history</td>
<td>Location of the history file</td>
</tr>
<tr>
<td>savehist</td>
<td>not set</td>
<td>Maximum number of events saved between sessions</td>
</tr>
</tbody>
</table>

**history and savehist**

When you exit from a `tcsh` shell, the most recently executed commands are saved in your `~/.history` file. The next time you start the shell this file initializes the history list. The value of the `savehist` variable determines the number of lines saved in the `.history` file (not necessarily the same as the `history` variable). If `savehist` is not set, `tcsh` does not save history between sessions. The `history` and `savehist` variables must be local (declared with `set`, not `setenv`). The `history` variable holds the number of events remembered during a session and the `savehist` variable holds the number remembered between sessions. See Table 9-2.

If you set the value of `history` too high, it can use too much memory. If it is unset or set to zero, the shell does not save any commands. To establish a history list of the 500 most recent events, give the following command manually or place it in your `~/.tcshrc` startup file:

```bash
tcsh $ set history = 500
```

The following command causes `tcsh` to save the 200 most recent events across login sessions:
tcsh $ set savehist = 200

You can combine these two assignments into a single command:

tcsh $ set history=500 savehist=200

After you set savehist you can log out and log in again, and the 200 most recent events from the previous login sessions will appear in your history list. Set savehist in your ~/.tcshrc file if you want to maintain your event list from login to login.

histlit

If you set the variable histlit (history literal), history displays the commands in the history list exactly as they were typed in without any shell interpretation. The following example shows the effect of this variable (compare the lines numbered 32):

tcsh $ cat /etc/csh.cshrc
...
tcsh $ cp !!:1 ~

cp /etc/csh.cshrc ~
tcsh $ set histlit
tcsh $ history
...
    31  9:35    cat /etc/csh.cshrc
    32  9:35    cp !!:1 ~
    33  9:35    set histlit
    34  9:35    history
tcsh $ unset histlit
tcsh $ history
...
    31  9:35    cat /etc/csh.cshrc
    32  9:35    cp /etc/csh.cshrc ~
33 9:35  set histlit
34 9:35  history
35 9:35  unset histlit
36 9:36  history
There is a difference in how `bash` and `tcsh` expand history event designators. If you give the command `!250w`, `bash` replaces it with command number 250 with a character `w` appended to it. In contrast, `tcsh` looks back through your history list for an event that begins with the string `250w` to execute. The reason for the difference: `bash` interprets the first three characters of `250w` as the number of a command, whereas `tcsh` interprets those characters as part of the search string `250w`. (If the 250 stands alone, `tcsh` treats it as a command number.)

If you want to append `w` to command number 250, you can insulate the event number from the `w` by surrounding it with braces:

```
!{250}w
```

Aliases

The `alias/unalias` feature in `tcsh` closely resembles its counterpart in `bash` (page 312). However, the `alias` builtin has a slightly different syntax:

```
alias name value
```

The following command creates an alias for `ls`:

```
tcsh $ alias ls "ls -lF"
```

The `tcsh alias` allows you to substitute command line arguments, whereas `bash` does not:

```
$ alias nam "echo Hello, \!^ is my name"
$ nam Sam
Hello, Sam is my name
```

The string `\!*` within an alias expands to all command line arguments:

```
$ alias sortprint "sort \!* | lpr"
```

The next alias displays its second argument:

```
$ alias n2 "echo \!:2"
```
Special Aliases

Some alias names, called special aliases, have special meaning to tcsh. If you define an alias with one of these names, tcsh executes it automatically as explained in Table 9-3. Initially all special aliases are undefined.

<table>
<thead>
<tr>
<th>Alias</th>
<th>When executed</th>
</tr>
</thead>
<tbody>
<tr>
<td>beepcmd</td>
<td>Whenever the shell would normally ring the terminal bell. Gives you a way to have other visual or audio effects take place at those times.</td>
</tr>
<tr>
<td>cwdcmd</td>
<td>Whenever you change to another working directory.</td>
</tr>
<tr>
<td>periodic</td>
<td>Periodically, as determined by the number of minutes in the tperiod variable. If tperiod is unset or has the value 0, periodic has no meaning.</td>
</tr>
<tr>
<td>precmd</td>
<td>Just before the shell displays a prompt.</td>
</tr>
<tr>
<td>shell</td>
<td>Gives the absolute pathname of the shell that you want to use to run scripts that do not start with #! (page 265).</td>
</tr>
</tbody>
</table>

To see a list of current aliases, give the command alias. To view the alias for a particular name, give the command alias followed by the name.

History Substitution In Aliases

You can substitute command line arguments by using the history mechanism, where a single exclamation point represents the command line containing the alias. Modifiers are the same as those used by history (page 300). In the following example, the exclamation points are quoted so that the shell does not interpret them when building the aliases:

```
21 $ alias last echo 

22 $ last this is just a test

test

23 $ alias fn2 echo

24 $ fn2 /home/jenny/test /home/alex/temp /home/barbara/new

temp
```

Event 21 defines for last an alias that displays the last argument. Event 23 defines for fn2 an alias that displays the simple filename, or tail, of the second argument on the command line.

Job Control
Job control is similar in both bash (page 271) and tcsh. You can move commands between the foreground and background, suspend jobs temporarily, and get a list of the current jobs. The % character references a job when followed by a job number or a string prefix that uniquely identifies the job. You will see a minor difference when you run a multiple-process command line in the background from each shell. Whereas bash displays only the PID number of the last background process in each job, tcsh displays the numbers for all processes belonging to a job. The example from page 271 looks like this under tcsh:

```
tcsh $ find . -print | sort | lpr & grep -l alex /tmp/* > alexfiles &
```

```
[1] 18839  18840    18841
[2] 18876
```

### Filename Substitution

The TC Shell expands the characters *, ?, and [ ] in a pathname just as bash does (page 127). The * matches any string of zero or more characters, ? matches any single character, and [ ] defines a character class, which is used to match single characters appearing within a pair of brackets.

The TC Shell expands command line arguments that start with a tilde (~) into filenames in much the same way that bash does (page 351), with the ~ standing for the user's home directory or the home directory of the user whose name follows the tilde. The bash special expansions ~ + and ~ ✕ are not available in tcsh.

Brace expansion (page 324) is available in tcsh. Like tilde expansion, it is regarded as an aspect of filename substitution even though brace expansion can generate strings that are not the names of actual files.

In tcsh and its predecessor csh, the process of using patterns to match filenames is referred to as globbing and the pattern itself is called a globbing pattern. If tcsh is unable to identify one or more files that match a globbing pattern, it reports an error (unless the pattern contains a brace). Setting the shell variable noglob suppresses filename substitution, including both tilde and brace interpretation.

### Manipulating the Directory Stack

Directory stack manipulation in tcsh does not differ much from that in bash (page 274). The dirs builtin displays the contents of the stack, and the pushd and popd builtins push directories onto and pop directories off of the stack.

### Command Substitution

The $(...) format for command substitution is not available in tcsh. In its place you must use the original ' ... ' format. Otherwise, the implementation in bash and tcsh is identical. Refer to page 329 for more information on command substitution.

### Redirecting Standard Error

Both bash and tcsh use a greater than symbol (>) to redirect standard output, but tcsh does not use the bash
Both bash and tcsh use a greater than symbol (>) to redirect standard output, but tcsh does not use the bash notation 2> to redirect standard error. Under tcsh you use a greater than symbol followed by an ampersand (>&) to combine and redirect standard output and standard error. Although you can use this notation under bash, it is not common. The following examples, like the bash examples on page 261, reference file x, which does not exist, and file y, which contains a single line.

```
tcsh $ cat x
   cat: x: No such file or directory
```

```
tcsh $ cat y
   This is y.
```

```
tcsh $ cat x y >& hold
```

```
tcsh $ cat hold
   cat: x: No such file or directory
   This is y.
```

With an argument of y in the preceding example, cat sends a string to standard output. An argument of x causes cat to send an error message to standard error.

Unlike bash, tcsh does not provide a simple way to redirect standard error separately from standard output. A work-around frequently provides a reasonable solution. The following example runs cat with arguments of x and y in a subshell (the parentheses ensure that the command within them runs in a subshell—see page 270). Also within the subshell a > redirects standard output to the file outfile. Output sent to standard error is not touched by the subshell but rather is sent to the parent shell, where both it and standard output are sent to errfile. Because standard output has already been redirected, errfile contains only output sent to standard error.

```
tcsh $(cat x y > outfile) >& errfile
```

```
tcsh $ cat outfile
   This is y.
```

```
tcsh $ cat errfile
   cat: x: No such file or directory
```

It can be useful to combine and redirect output when you want to run a slow command in the background and do not want its output cluttering up the terminal screen. For example, because the find utility (page 655) often takes some time to complete, it may be a good idea to run it in the background. The next command finds in the filesystem hierarchy all files that contain the string biblio in their name. The command runs in the background and sends its output to the findout file. Because the find utility sends to standard error a report of directories that you do not have permission to search, the findout file contains a record of any files that are found as well as a record of the directories that could not be searched.

```
tcsh $(find . -name *biblio* > findout) >& errfile
```

```
tcsh $ cat findout
```

```
tcsh $ cat errfile
   cat: x: No such file or directory
```
tcsh $ find / -name "*biblio*" -print >& findout &

In this example, if you did not combine standard error with standard output and redirected only standard output, the error messages would appear on the screen and `findout` would list only files that were found.

While a command that has its output redirected to a file is running in the background, you can look at the output by using `tail` (page 783) with the `-f` option. The `-f` option causes `tail` to display new lines as they are written to the file:

```
tcsh $ tail -f findout
```

To terminate the `tail` command, press the interrupt key (usually CONTROL-C).

---

**Working with the Command Line**

This section covers word completion, editing the command line, and correcting spelling.

**Word Completion**

The TC Shell completes filenames, commands, and variable names on the command line when you prompt it to do so. The generic term used to refer to all these features under `tcsh` is *word completion*.

**Filename Completion**

The TC Shell can complete a filename after you specify a unique prefix. Filename completion is similar to filename generation, but the goal of filename completion is to select a single file. Together they make it practical to use long, descriptive filenames.

To use filename completion when you are entering a filename on the command line, type enough of the name to identify the file in the directory uniquely and press TAB; `tcsh` fills in the name and adds a SPACE, leaving the cursor so you can enter additional arguments or press RETURN. In the following example, the user types the command `cat trig1A` and presses TAB; the system fills in the rest of the filename that begins with `trig1A`:

```
tcsh $ cat trig1A
```

If two or more filenames match the prefix that you have typed, `tcsh` cannot complete the filename without obtaining more information from you. The shell attempts to maximize the length of the prefix by adding characters, if possible, and then beeps to signify that additional input is needed to resolve the ambiguity:
tcsh $ ls h*

help.hist  help.trig01  help.txt

tcsh $ cat h

TAB

TAB

cat help. (beep)

You can fill in enough characters to resolve the ambiguity and then press the TAB key again. Alternatively, you can press CONTROL-D to cause tcsh to display a list of matching filenames:

tcsh $ cat help.

CONTROL-D

help.hist  help.trig01  help.txt

tcsh $ cat help.

After displaying the filenames tcsh redraws the command line so you can disambiguate the filename (and press TAB again) or finish typing the filename manually.

Tilde Completion

The TC Shell parses a tilde (~) appearing as the first character of a word and attempts to expand it to a username when you enter a TAB:

tcsh $ cd ~al

TAB

cd ~alex/

RETURN

tcsh $ pwd

/home/alex

By appending a slash (/), tcsh indicates that the completed word is a directory. The slash also makes it easy to continue specifying the pathname.

Command and Variable Completion
You can use the same mechanism that you use to list and complete filenames with command and variable names. Unless you give a full pathname, the shell uses the variable `path` in an attempt to complete a command name. The choices listed are likely to be located in different directories.

```
tcsh $ up
   TAB
   (beep)
   CONTROL-D
```

```
up2date               updatedb              uptime
up2date-config        update-mime-database
up2date-nox           updmap
```

```
tcsh $ up
   t
   TAB
   uptime
   RETURN
```

9:59am up 31 days, 15:11, 7 users, load average: 0.03, 0.02, 0.00

If you set the `autolist` variable as in the following example, the shell lists choices automatically when you invoke completion by pressing TAB. You do not have to press CONTROL-D.

```
tcsh $ set autolist
```

```
tcsh $ up
   TAB
   (beep)
```

```
up2date               updatedb              uptime
up2date-config        update-mime-database
up2date-nox           updmap
```

```
tcsh $ up
   t
   TAB
   uptime
   
   
   
   RETURN
```
If you set `autolist` to `ambiguous`, the shell lists the choices when you press `TAB only` if the word you enter is the longest prefix of a set of commands. Otherwise, pressing `TAB` causes the shell to add one or more characters to the word until it is the longest prefix; pressing `TAB` again then lists the choices:

```
tcsh $ set autolist=ambiguous

tcsh $ echo $h
   →
   TAB
      (beep)

histfile history home

tcsh $ echo $h
   →
   i
   →
   TAB
      echo $hist
      →
      TAB

histfile history

tcsh $ echo $hist
   →
   o
   →
   TAB
      echo $history
      →

RETURN

1000
```

The shell must rely on the context of the word within the input line to determine whether it is a filename, a username, a command, or a variable name. The first word on an input line is assumed to be a command name; if a word begins with the special character `$`, it is viewed as a variable name; and so on. In the following example, the second `which` command does not work properly: The context of the word `up` makes it look like the beginning of a filename rather than the beginning of a command. The TC Shell supplies `which` with an argument of `updates` (a nonexecutable file) and `which` displays an error message:

```
tcsh $ ls up*
```
updates

tcsh $ which updatedb ups uptime
/usr/bin/updatedb
/usr/local/bin/ups
/usr/bin/uptime

tcsh $ which up
TAB which updates

updates: Command not found.

Editing the Command Line

bindkey

The tcsh command line editing feature is similar to that available under bash. You can use either emacs mode commands (default) or vi(m) mode commands. Change to vi(m) mode commands by using bindkey v and to emacs mode commands by using bindkey e. The ARROW keys are bound to the obvious motion commands in both modes, so you can move back and forth (up and down) through your history list as well as left and right on the current command line.

Without an argument, the bindkey builtin displays the current mappings between editor commands and the key sequences you can enter at the keyboard:

tcsh $ bindkey

Standard key bindings

"^@" -> set-mark-command
"^A" -> beginning-of-line
"^B" -> backward-char
"^C" -> tty-sigintr
"^D" -> delete-char-or-list-or-eof
...

Multi-character bindings
Arrow key bindings

down           -> down-history
up             -> up-history
left           -> backward-char
right          -> forward-char
home           -> beginning-of-line
end            -> end-of-line

The ^ indicates a CONTROL character (^B = CONTROL-B). The ^[ indicates a META or ALT character; you press and hold the META or ALT key while you press the key for the next character. If this substitution does not work or if the keyboard you are using does not have a META or ALT key, press and release the ESCAPE key and then press the key for the next character. For ^[[F you would press META-[ or ALT-[ followed by the F key or else ESCAPE [ F). The down/up/left/right indicate ARROW keys, and home/end indicate the HOME and END keys on the numeric keypad.

The preceding example shows the output from bindkey with the user in emacs mode. Change to vi(m) mode (bindkey [v) and give another bindkey command to display the vi(m) key bindings. You can pipe the output of bindkey through less to make it easier to read the list.

Correcting Spelling

You can have tcsh attempt to correct the spelling of command names, filenames, and variables (but only using emacs-style key bindings). Spelling correction can take place only at two times: before and after you press RETURN.

before you press return

For tcsh to correct a word or line before you press RETURN, you must indicate that you want it to do so. The two functions for this purpose are spell-line and spell-word:
$ bindkey | grep spell

"^["     -> spell-line
"^[S"      -> spell-word
"^[s"      -> spell-word

The output from bindkey shows that spell-line is bound to META-$ (ALT-$ or ESCAPE $) and spell-word is bound to META-S and META-s (ALT-s or ESCAPE s and ALT-S or ESCAPE S). To correct the spelling of the word to the left of the cursor, enter META-s. Entering META-$ invokes the spell-line function, which attempts to correct all words on a command line:

tcsh $ ls

bigfile.gz

tcsh $ gunzipp

   META-s
   gunzip bigfele.gz
       META-s
   gunzip bigfile.gz

tcsh $ gunzip bigfele.gz

   META-S
   gunzip bigfile.gz

tcsh $ echo $user

A
fter You Press Return

The variable named correct controls what tcsh attempts to correct or complete after you press RETURN and before it passes the command line to the command being called. If you do not set correct, tcsh will not correct anything:

tcsh $ unset correct

tcsh $ ls morning

morning
The shell reports the error in the variable name and not the command name because it expands variables before it executes the command (page 344). When you give a bad command name without any arguments, the shell reports on the bad command name.

Set `correct` to `cmd` to correct only commands; `all` to correct commands, variables, and filenames; or `complete` to complete commands:

```
tcsh $ set correct = cmd
tcsh $ echo $usfr morging
```

```
CORRECT>echo $usfr morging (y|n|e|a)? y
usfr: Undefined variable.
tcsh $ set correct = all
tcsh $ echo $usfr morging
```

```
CORRECT>echo $user morning (y|n|e|a)? y
alex morning
```

With `correct` set to `cmd`, `tcsh` corrects the command name from `echo` to `echo`. With `correct` set to `all`, `tcsh` corrects both the command name and the variable. It would also correct a filename if one was present on the command line.

Automatic spell checking displays a special prompt that lets you enter `y` to accept the modified command line, `n` to reject it, `e` to edit it, or `a` to abort the command. Refer to "prompt3" on page 364 for a discussion of the special prompt used in spelling correction.

In the next example, after setting the `correct` variable the user mistypes the name of the `ls` command; `tcsh` then prompts for a correct command name. Because the command that `tcsh` has offered as a replacement is not `ls`, the user chooses to edit the command line. The shell leaves the cursor following the command so the user can correct the mistake:

```
tcsh $ set correct=cmd
tcsh $ lx -l
```
If you assign the value `complete` to the variable `correct`, `tcsh` attempts command name completion in the same manner as filename completion (page 350). In the following example, after setting `correct` to `complete` the user enters the command `up`. The shell responds with **Ambiguous command** because several commands start with these two letters but differ in the third letter. The shell then redisplay the command line. The user could press TAB at this point to get a list of commands that start with `up` but decides to enter `t` and press RETURN. The shell completes the command because these three letters uniquely identify the `uptime` utility:

```
tcsh $ set correct = complete
tcsh $ up  
Ambiguous command
  tcsh $ up ->
     t       RETURN
           --> uptime
4:45pm  up 5 days,  9:54,  5 users,  load average: 1.62, 0.83, 0.33
```

**Variables**

Although `tcsh` stores variable values as strings, you can work with these variables as numbers. Expressions in `tcsh` can use arithmetic, logical, and conditional operators. The `@` builtin can evaluate integer arithmetic expressions.

This section uses the term **numeric variable** to describe a string variable that contains a number that `tcsh` uses in arithmetic or logical arithmetic computations. However, no true numeric variables exist in `tcsh`.

**Variable name**

A `tcsh` variable name consists of 1 to 20 characters, which can be letters, digits, and underscores (_). The first character cannot be a digit but can be an underscore.

**Variable Substitution**

Three builtins declare, display, and assign values to variables: `set`, `@`, and `setenv`. The `set` and `setenv` builtins both assume nonnumeric string variables. The `@` builtin works only with numeric variables. Both `set` and `@` declare local variables. The `setenv` builtin declares a variable and places it in the calling environment of all child
processes (makes it global). Using setenv is similar to assigning a value to a variable and then using export in the Bourne Again Shell. See "Locality of Variables" on page 475 for a discussion of local and environment variables.

Once the value—or merely the existence—of a variable has been established, tcsh substitutes the value of that variable when the name of the variable, preceded by a dollar sign ($), appears on a command line. If you quote the dollar sign by preceding it with a backslash or enclosing it within single quotation marks, the shell does not perform the substitution. When a variable is within double quotation marks, the substitution occurs even if you quote the dollar sign by preceding it with a backslash.

### String Variables

The TC Shell treats string variables similarly to the way the Bourne Again Shell does. The major difference is in their declaration and assignment: tcsh uses an explicit command, set (or setenv), to declare and/or assign a value to a string variable.

```
tcsh $ set name = fred

tcsh $ echo $name
fred

tcsh $ set
argv    ()
cwd     /home/alex
cwd     /home/alex
name    fred
path    (/usr/local/bin /bin /usr/bin /usr/X11R6/bin)
prompt  $
shell   /bin/tcsh
status  0
term    vt100
user    alex
```

The first line in the example declares the variable name and assigns the string fred to it. Unlike bash, tcsh allows but does not demand SPACES around the equal sign. The next line displays this value. When you give a set command without any arguments, it displays a list of all local shell variables and their values (your list will be longer than the one in the example). When you give a set command with the name of a variable and no value, the command sets the value of the variable to a null string.
You can use the `unset` builtin to remove a variable:

```
tcsh $ set name
```
```
tcsh $ echo $name
```
```
tcsh $ unset name
```
```
tcsh $ echo $name
name: Undefined variable.
```

With `setenv` you must separate the variable name from the string being assigned to it by one or more SPACEs and no equal sign. The `tcsh` command creates a subshell, `echo` shows that the variable and its value are known to the subshell, and `exit` returns to the original shell. Try this example, using `set` in place of `setenv`:

```
tcsh $ setenv SCRDIR /usr/local/src
```
```
tcsh $ tcsh
```
```
tcsh $ echo $SCRDIR
/usr/local/src
```
```
tcsh $ exit
```

If you use `setenv` with no arguments, it displays a list of the environment (global) variables that are passed to the shell's child processes. By convention, environment variables are named using uppercase letters.

As with `set`, giving `setenv` a variable name without a value sets the value of the variable to a null string. Although you can use `unset` to remove environment and local variables, `unsetenv` can remove only environment variables.

### Arrays of String Variables

An *array* is a collection of strings, each of which is identified by its index (1, 2, 3, and so on). Arrays in `tcsh` use one-based indexing (the first element of the array has the subscript 1). Before you can access individual elements of an array, you must declare the entire array by assigning a value to each element of the array. The list of values must be enclosed in parentheses and separated by SPACEs:

```
8 $ set colors = (red green blue orange yellow)
```
```
9 $ echo $colors
```
```
red green blue orange yellow
```
10 $ echo $colors[3]
blue
11 $ echo $colors[2-4]
green blue orange
12 $ set shapes = ('' '' '' '' ')
13 $ echo $shapes

14 $ set shapes[4] = square
15 $ echo $shapes[4]
square

Event 8 declares the array of string variables named colors to have five elements and assigns values to each of them. If you do not know the values of the elements at the time you declare an array, you can declare an array containing the necessary number of null elements (event 12).

You can reference an entire array by preceding its name with a dollar sign (event 9). A number in brackets following a reference to the array refers to an element of the array (events 10, 14, and 15). Two numbers in brackets, separated by a hyphen, refer to two or more adjacent elements of the array (event 11). Refer to "Special Variable Forms" on page 361 for more information on arrays.

Numeric Variables

The @ builtin assigns the result of a numeric calculation to a numeric variable (as described under "Variables" [page 355], tcsh has no true numeric variables). You can declare single numeric variables with @, just as you can use set to declare nonnumeric variables. However, if you give it a nonnumeric argument, @ displays an error message. Just as set does, the @ command used without any arguments lists all shell variables.

Many of the expressions that the @ builtin can evaluate and the operators it recognizes are derived from the C programming language. The following format shows a declaration or assignment using @ (the SPACE after the @ is required):

    @ variable-name operator expression

The variable-name is the name of the variable that you are assigning a value to. The operator is one of the C assignment operators: =, +=, -=, *=, /=, or %= (See page 533 for an explanation of these operators.) The expression is an arithmetic expression that can include most C operators (see the next section). You can use parentheses within the expression for clarity or to change the order of evaluation. Parentheses must surround parts of the expression that contain any of the following characters: <, >, &, or |.
Expressions

An expression is composed of constants, variables, and most any of the bash operators (page 505). Expressions that involve files rather than numeric variables or strings are described in Table 9-8 on page 368.

<table>
<thead>
<tr>
<th>n</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>File is a block special file</td>
</tr>
<tr>
<td>c</td>
<td>File is a character special file</td>
</tr>
<tr>
<td>d</td>
<td>File is a directory file</td>
</tr>
<tr>
<td>e</td>
<td>File exists</td>
</tr>
<tr>
<td>f</td>
<td>File is an ordinary or directory file</td>
</tr>
<tr>
<td>g</td>
<td>File has the set-group-ID bit set</td>
</tr>
<tr>
<td>k</td>
<td>File has the sticky bit (page 903) set</td>
</tr>
<tr>
<td>l</td>
<td>File is a symbolic link</td>
</tr>
<tr>
<td>o</td>
<td>File is owned by user</td>
</tr>
<tr>
<td>p</td>
<td>File is a named pipe (FIFO)</td>
</tr>
<tr>
<td>r</td>
<td>The user has read access to the file</td>
</tr>
<tr>
<td>s</td>
<td>File is not empty (has nonzero size)</td>
</tr>
<tr>
<td>S</td>
<td>File is a socket special file</td>
</tr>
<tr>
<td>t</td>
<td>File descriptor (a single digit replacing filename) is open and connected to the screen</td>
</tr>
<tr>
<td>u</td>
<td>File has the set-user-ID bit set</td>
</tr>
<tr>
<td>w</td>
<td>User has write access to the file</td>
</tr>
<tr>
<td>x</td>
<td>User has execute access to the file</td>
</tr>
<tr>
<td>X</td>
<td>File is either a builtin or an executable found by searching the directories in Spath</td>
</tr>
<tr>
<td>z</td>
<td>File is 0 bytes long</td>
</tr>
</tbody>
</table>

Expressions follow these rules:

1. The shell evaluates a missing or null argument as 0.

2. All results are decimal numbers.

3. Except for != and = =, the operators act on numeric arguments.

4. You must separate each element of an expression from adjacent elements by a SPACE, unless the adjacent element is &, |, <, >, (, or ).

**tip: Do not use $ when assigning a value to a variable**

As with bash, variables having a value assigned to them (those on the left of the operator) must not be preceded by a dollar sign ($). Thus

```
tcsh $ @ Sanswer = 5 + 5
```

will yield
answer: Undefined variable.

or, if answer is defined,

    @: Variable name must begin with a letter.

whereas

tcsh $ @ answer = 5 + 5

assigns the value 10 to the variable answer.

Following are some examples that use @:

    216 $ @ count = 0
    217 $ echo $count
        0
    218 $ @ count = ( 10 + 4 ) / 2
    219 $ echo $count
        7
    220 $ @ result = ( $count < 5 )
    221 $ echo $result
        0
    222 $ @ count += 5
    223 $ echo $count
        12
    224 $ @ count++
    225 $ echo $count
        13
Event 216 declares the variable \texttt{count} and assigns it a value of 0. Event 218 shows the result of an arithmetic operation being assigned to a variable. Event 220 uses @ to assign the result of a logical operation involving a constant and a variable to \texttt{result}. The value of the operation is \texttt{false} (= 0) because the variable \texttt{count} is not less than 5. Event 222 is a compressed form of the following assignment statement:

\begin{verbatim}
tcsh $ @ count = $count + 5
\end{verbatim}

Event 224 uses a postfix operator to increment \texttt{count} by 1.

\textbf{Postincrement and postdecrement operators}

You can use the postincrement (++) and postdecrement (--) operators only in expressions containing a single variable name, as shown in the following example:

\begin{verbatim}
tcsh $ @ count = 0
tcsh $ @ count++
tcsh $ echo $count
1
tcsh $ @ next = $count++
@: Badly formed number.
\end{verbatim}

Unlike in the C programming language and \texttt{bash}, expressions in \texttt{tcsh} cannot use preincrement and predecrement operators.

\textbf{Arrays of Numeric Variables}

You must use the \texttt{set} builtin to declare an array of numeric variables before you can use @ to assign values to the elements of that array. The \texttt{set} builtin can assign any values to the elements of a numeric array, including zeros, other numbers, and null strings.

Assigning a value to an element of a numeric array is similar to assigning a value to a simple numeric variable. The only difference is that you must specify the element, or index, of the array. The syntax is

\begin{verbatim}
@ variable-name
[ index ]
operator expression
\end{verbatim}

The \texttt{index} specifies the element of the array that is being addressed. The first element has an index of 1.
The index specifies the element of the array that is being addressed. The first element has an index of 1. The index cannot be an expression but must be either a numeric constant or a variable. In the preceding syntax the brackets around index are part of the syntax and do not indicate that index is optional. If you specify an index that is too large for the array you declared with set, tcsh displays @: Subscript out of range.

```
226 $ set ages = (0 0 0 0 0)
227 $ @ ages[2] = 15
228 $ @ ages[3] = ($ages[2] + 4)
229 $ echo $ages[3]
19
230 $ echo $ages
0 15 19 0 0
231 $ set index = 3
232 $ echo $ages[$index]
19
233 $ echo $ages[6]
ages: Subscript out of range.
```

Elements of a numeric array behave as though they were simple numeric variables. Event 226 declares an array with five elements, each having a value of 0. Events 227 and 228 assign values to elements of the array, and event 229 displays the value of one of the elements. Event 230 displays all the elements of the array, 232 specifies an element by using a variable, and 233 demonstrates the out-of-range error message.

**Braces**

Like with bash, tcsh allows you to use braces to distinguish a variable from surrounding text without the use of a separator:

```
$ set bb=abc
$ echo $bbdef
bbdef: Undefined variable.
$ echo ${bb}def
abcdef
```
Special Variable Forms

The special variable with the following syntax has the value of the number of elements in the `variable-name` array:

```
$# variable-name
```

You can determine whether `variable-name` has been set by looking at the value of the variable with the following syntax:

```
$? variable-name
```

This variable has a value of 1 if `variable-name` is set and 0 otherwise:

```
tcsh $ set days = (mon tues wed thurs fri)
tcsh $ echo $#days
5
tcsh $ echo $?days
1
tcsh $ unset days
tcsh $ echo $?days
0
```

Reading User Input

Within a `tcsh` shell script, you can use the `set` builtin to read a line from the terminal and assign it to a variable. The following portion of a shell script prompts the user and reads a line of input into the variable `input_line`:

```
echo -n "Enter input: "
set input_line = "$<"
```

The value of the shell variable `$<` is a line from standard input. The quotation marks around `$<` keep the shell from assigning only the first word of the line of input to the variable `input_line`.

Shell Variables
TC Shell variables may be set by the shell, inherited by the shell from the environment, or set by the user and used by the shell. Some variables take on significant values (for example, the PID number of a background process). Other variables act as switches: on if they are declared and off if they are not. Many of the shell variables are often set from one of tcsh's two startup files: ~/.login and ~/.tcshrc (page 342).

Shell Variables That Take On Values

**argv**

Contains the command line arguments (positional parameters) from the command line that invoked the shell. Like all tcsh arrays, this array uses one-based indexing; argv[1] contains the first command line argument. You can abbreviate references to $argv[n] as $n. The token argv[*] references all the arguments together; you can abbreviate it as $*. Use $0 to reference the name of the calling program. Refer to "Positional Parameters" on page 480. The Bourne Again Shell does not use the argv form, only the abbreviated form.

**$#argv or $#**

Holds the number of elements in the argv array. Refer to "Special Variable Forms" on page 361.

**autolist**

Controls command and variable completion (page 351).

**autologout**

Enables tcsh's automatic logout facility, which logs you out if you leave the shell idle for too long. The value of the variable is the number of minutes of inactivity that tcsh waits before logging you out. The default is 60 minutes if you are Superuser. This variable is initially unset for other users.

**cdpath**

Affects the operation of cd in the same way as the CDPATH variable does in bash (page 289). The cdpath variable is assigned an array of absolute pathnames (see path, later in this section) and is usually set in the ~/.login file with a command line such as the following:

```
tcsh $ set cdpath = (/home/scott /home/scott/letters)
```

When you call cd with a simple filename, it searches the working directory for a subdirectory with that name. If one is not found, cd searches the directories listed in cdpath for the subdirectory.

**correct**

Set to cmd for automatic spelling correction of command names, to all to correct the entire command line, and to complete for automatic completion of command names. This variable works on corrections that are made after you press RETURN. Refer to "After You Press RETURN" on page 354.

**cwd**

The shell sets this variable to the name of the working directory. When you access a directory through a symbolic link (page 99), tcsh sets cwd to the name of the symbolic link.

**distack**

The shell keeps the stack of directories used with the pushd, popd, and dirs builtins in this variable. For more information refer to "Manipulating the Directory Stack" on page 274.

**fgignore**

Holds an array of suffixes that tcsh ignores during filename completion.

**gid**

The shell sets this variable to your group ID.

**histfile**

Holds the full pathname of the file that saves the history list between login sessions (page 345). The defaults is ~/.history.

**history**

Specifies the size of your history list. Refer to "History" on page 344.

**home or HOME**

Holds the pathname of the user's home directory. The cd builtin refers to this variable, as does the filename substitution of ~ (page 326).

**mail**

Specifies files and directories to check for mail. The TC Shell checks for new mail every 10 minutes unless the first word of mail is a number, in which case that number specifies how often the shell should check in seconds.

**owd**

The shell keeps the name of your previous (old) working directory in this variable, which is
The shell keeps the name of your previous (old) working directory in this variable, which is equivalent to ~ in bash.

**path or PATH** Holds a list of directories that tcsh searches for executable commands (page 284). If this array is empty or unset, you can execute commands only by giving their full pathnames. You can set path with a command such as the following:

```
tcsh $ set path = ( /usr/bin /bin /usr/local/bin
   /usr/bin/X11 ~/bin . )
```

**prompt** Holds the primary prompt, similar to the bash PS1 variable (page 286). If it is not set, the prompt is >, or # for root (Superuser). The shell expands an exclamation point in the prompt string to the current event number. The following is a typical line from a .tcshrc file that sets the value of prompt:

```
set prompt = '!' $ '
```

Table 9-4 lists a number of special formatting sequences you can use in prompt to achieve special effects.

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Displays in prompt</th>
</tr>
</thead>
<tbody>
<tr>
<td>%/</td>
<td>Value of cwd (the working directory)</td>
</tr>
<tr>
<td>%~</td>
<td>Same as %/, but replaces the path of the user's home directory with a tilde</td>
</tr>
<tr>
<td>%! or %h or !</td>
<td>Current event number</td>
</tr>
<tr>
<td>%m</td>
<td>Hostname without the domain</td>
</tr>
<tr>
<td>%M</td>
<td>Full hostname, including the domain</td>
</tr>
<tr>
<td>%n</td>
<td>User's username</td>
</tr>
<tr>
<td>%t</td>
<td>Time of day through the current minute</td>
</tr>
<tr>
<td>%p</td>
<td>Time of day through the current second</td>
</tr>
<tr>
<td>%d</td>
<td>Day of the week</td>
</tr>
<tr>
<td>%D</td>
<td>Day of the month</td>
</tr>
<tr>
<td>%W</td>
<td>Month as mm</td>
</tr>
<tr>
<td>%y</td>
<td>Year as yy</td>
</tr>
<tr>
<td>%Y</td>
<td>Year as yyyy</td>
</tr>
<tr>
<td>%#</td>
<td>A pound sign (#) if the user is running as root (Superuser); otherwise a greater than sign (&gt;)</td>
</tr>
<tr>
<td>%?</td>
<td>Exit status of the preceding command</td>
</tr>
</tbody>
</table>

**prompt2** Holds the prompt used in foreach and while control structures (pages 373 and 375). The default value is '%%R? ', where R is replaced by the word while if you are inside a while structure and foreach if you are inside a foreach structure.

**prompt3** Holds the prompt used during automatic spelling correction. The default value is 'CORRECT>%%R (y|n|e|a)?', where R is replaced by the corrected string.

**savehist** Specifies the number of commands saved from the history list when you log out. These events are saved in a file named ~/.history. The shell uses these events as the initial history list when you log in again,
causing your history list to continue across login sessions (page 345).

**shell**  
Holds the pathname of the shell you are using.

**shlvl**  
Is incremented each time you start a subshell and decremented each time you exit a subshell. The value is set to 1 for login a shell.

**status**  
Contains the exit status returned by the last command. Similar to $? in bash (page 479).

**tcsh**  
Holds the version number of tcsh that you are running.

**time**  
Provides two functions: automatic timing of commands using the time builtin and the format used by time. You can set this variable to either a single numeric value or an array holding a numeric value and a string. The numeric value is used to control automatic timing; any command that takes more than that number of CPU seconds to run has time display the command statistics when it finishes execution. A value of 0 results in statistics being displayed after every command. The string controls the formatting of the statistics using special formatting sequences, including those listed in Table 9-5.

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>%U</td>
<td>Time the command spent running user code, in CPU seconds (user mode)</td>
</tr>
<tr>
<td>%S</td>
<td>Time the command spent running system code, in CPU seconds (kernel mode)</td>
</tr>
<tr>
<td>%E</td>
<td>Wall clock time (total elapsed) taken by the command</td>
</tr>
<tr>
<td>%P</td>
<td>Percentage of time the CPU spent on this task during this period, computed as (%U+%S)/%E</td>
</tr>
<tr>
<td>%W</td>
<td>Number of times the command's processes were swapped out to disk</td>
</tr>
<tr>
<td>%X</td>
<td>Average amount of shared code memory used by the command, in kilobytes</td>
</tr>
<tr>
<td>%D</td>
<td>Average amount of data memory used by the command, in kilobytes</td>
</tr>
<tr>
<td>%K</td>
<td>Total memory used by the command (as %X+%D), in kilobytes</td>
</tr>
<tr>
<td>%M</td>
<td>Maximum amount of memory used by the command, in kilobytes</td>
</tr>
<tr>
<td>%F</td>
<td>Number of major page faults (pages of memory that had to be read from disk)</td>
</tr>
<tr>
<td>%I</td>
<td>Number of input operations</td>
</tr>
<tr>
<td>%O</td>
<td>Number of output operations</td>
</tr>
</tbody>
</table>

By default the time builtin uses the string

```
"%Uu %Ss %E %P%  %X+%Dk %I+%Oio %Fpf+%Ww"
```

which generates output in the following format:

```
tcsh $ time
0.200u 0.340s 17:32:33.27 0.0% 0+0k 0+0io 1165pf+0w
```

You can time commands when you are concerned about system performance. If your commands consistently show many page faults and swaps, your system is probably memory starved and you should consider adding more memory to the system. You can use the information that time reports to compare the performance of various system configurations and program algorithms.

**tperiod**  
Controls how often, in minutes, the shell executes the special periodic alias (page 347).
user  The shell sets this variable to your username.

version The shell sets this variable to contain detailed information about the version of tcsh you are using.

watch Set to an array of user and terminal pairs to watch for logins and logouts. The word any means any user or any terminal, so (any any) monitors all logins and logouts on all terminals, and (scott ttyS1 any console $user any) watches for scott on ttyS1, any user who accesses the system console, and any logins and logouts that use your account (presumably to catch intruders). By default logins and logouts are checked once every 10 minutes, but you can change this value by beginning the array with a numeric value giving the number of minutes between checks. If you set watch to (1 any console), logins and logouts by any user on the console will be checked once a minute. Reports are displayed just before a new shell prompt is issued. Also, the log builtin forces an immediate check whenever it is executed. See who for information about how you can control the format of the watch messages.

who Controls the format of the information displayed in watch messages (Table 9-6).

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>%n</td>
<td>Username</td>
</tr>
<tr>
<td>%a</td>
<td>Action taken by user</td>
</tr>
<tr>
<td>%l</td>
<td>Terminal on which action took place</td>
</tr>
<tr>
<td>%M</td>
<td>Full hostname of remote host (or local if none) from which action took place</td>
</tr>
<tr>
<td>$m</td>
<td>Hostname without domain name</td>
</tr>
</tbody>
</table>

The default string used for watch messages when who is unset is "%n has %a %l from %m", which generates the following line:

jenny has logged on tty2 from local

$ As in bash, this variable contains the PID number of the current shell; use it as $$. 

Shell Variables That Act as Switches

The following shell variables act as switches; their values are not significant. If the variable has been declared, the shell takes the specified action. If not, the action is not taken or is negated. You can set these variables in your ~/.tcshrc startup file, in a shell script, or from the command line.

autocorrect Causes the shell to attempt spelling correction automatically, just before each attempt at completion.

dunique Normally pushd blindly pushes the new working directory onto the directory stack, meaning that you can end up with many duplicate entries on this stack. Set dunique to cause the shell to look for and delete any entries that duplicate the one it is about to push.

echo Causes the shell to display each command before it executes that command. Set echo by calling tcsh with the Ix option or by using set.

filec Enables filename completion (page 350) when running tcsh as csh (and csh is linked to tcsh).

histlit Displays the commands in the history list exactly as entered, without interpretation by the shell (page 346).

ignoreeof Prevents you from using CONTROL-D to exit from a shell so you cannot accidentally log out. When this variable is declared, you must use exit or logout to leave a shell.
**listjobs**
Causes the shell to list all jobs whenever a job is suspended.

**listlinks**
Causes the `ls -F` builtin to show the type of file each symbolic link points to instead of marking the symbolic link with an `@` symbol.

**loginsh**
Set by the shell if the current shell is running as a login shell.

**nobeep**
Disables all beeping by the shell.

**noclobber**
Prevents you from accidentally overwriting a file when you redirect output and prevents you from creating a file when you attempt to append output to a nonexistent file (Table 9-7). To override **noclobber**, add an exclamation point to the symbol you use for redirecting or appending output (for example, `>`! and `>>!`). For more information see page 119.

**Table 9-7. How noclobber works**

<table>
<thead>
<tr>
<th>Command line</th>
<th>noclobber not declared</th>
<th>noclobber declared</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x &gt; fileout</code></td>
<td>Redirects standard output from process <code>x</code> to <code>fileout</code>. Overwrites <code>fileout</code> if it exists.</td>
<td>Redirects standard output from process <code>x</code> to <code>fileout</code>. The shell displays an error message if <code>fileout</code> exists and does not overwrite the file.</td>
</tr>
<tr>
<td><code>x &gt;&gt; fileout</code></td>
<td>Redirects standard output from process <code>x</code> to <code>fileout</code>. Appends new output to the end of <code>fileout</code> if it exists. Creates <code>fileout</code> if it does not exist.</td>
<td>Redirects standard output from process <code>x</code> to <code>fileout</code>. Appends new output to the end of <code>fileout</code> if it exists. The shell displays an error message if <code>fileout</code> does not exist and does not create the file.</td>
</tr>
</tbody>
</table>

**noglob**
Prevents the shell from expanding ambiguous filenames. Allows you to use `*`, `?`, `~`, and `[ ]` on the command line or in a shell script without quoting them.

**nonomatch**
Causes the shell to pass an ambiguous file reference that does not match a filename to the command that is being called. The shell does not expand the file reference. When you do not set **nonomatch**, **tcsh** generates a No match error message and does not execute the command.

```
tcsh $ cat questions?
```

```
cat: No match
```

```
tcsh $ set nonomatch
```

```
tcsh $ cat questions?
```

```
cat: questions?: No such file or directory
```

**notify**
When set, **tcsh** sends a message to the screen immediately whenever a background job completes. Ordinarily **tcsh** notifies you about job completion just before displaying the next prompt. Refer to "Job Control" on page 271.

**pushdtohome**
Causes a call to `pushd` without any arguments to change directories to your home directory (equivalent to `pushd ~`).

**pushdsilent**
Causes `pushd` and `popd` not to display the directory stack.

**rmstar**
Causes the shell to request confirmation when you give an `rm *` command.

**verbose**
Causes the shell to display each command after a history expansion (page 344). Set **verbose** by calling **tcsh** with the `v` option or by using `set`.

**visiblebell**
Causes audible beeps to be replaced by flashing the screen.
The TC Shell uses many of the same control structures as the Bourne Again Shell. In each case the syntax is different, but the effects are the same. This section summarizes the differences between the control structures in the two shells. For more information refer to "Control Structures" on page 436.

## if

The syntax of the `if` control structure is

```plaintext
if ( expression )
    simple-command
```

The `if` control structure works only with simple commands, not with pipes or lists of commands. You can use the `if...then` control structure (page 372) to execute more complex commands.

### Example

```bash
tcsh $ cat if_1
#!/bin/tcsh
# Routine to show the use of a simple if control structure.
#
if ( $#argv == 0 ) echo "if_1: there are no arguments"
```

The `if_1` script checks whether it was called without any arguments. If the expression enclosed in parentheses evaluates to `true` (that is, if zero arguments were on the command line) the `if` structure displays a message.

In addition to logical expressions such as the one the `if_1` script uses, you can use expressions that return a value based on the status of a file. The syntax for this type of expression is

```plaintext
n filename
```

where `n` is from the list in Table 9-8.

If the result of the test is `true`, the expression has a value of 1; if it is `false`, the expression has a value of 0. If the specified file does not exist or is not accessible, `tcsh` evaluates the expression as 0. The following example checks whether the file specified on the command line is an ordinary or directory file (and not a device or other special file):

```bash
tcsh $ cat if_2
#!/bin/tcsh
```

### Example

```bash
tcsh $ cat if_2
```
if -f $1 echo "Ordinary or Directory file"

You can combine operators where it makes sense. For example, `ox filename` is `true` if you own and have execute permission for the file. This expression is equivalent to `o filename && ox filename`.

Some operators return useful information about a file other than reporting `true` or `false`. They use the same `n filename` format, where `n` is one of the values shown in Table 9-9.

<table>
<thead>
<tr>
<th><code>n</code></th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>The last time the file was accessed. [*]</td>
</tr>
<tr>
<td>A:</td>
<td>The last time the file was accessed displayed in a human-readable format.</td>
</tr>
<tr>
<td>M</td>
<td>The last time the file was modified. [*]</td>
</tr>
<tr>
<td>M:</td>
<td>The last time the file was modified displayed in a human-readable format.</td>
</tr>
<tr>
<td>C</td>
<td>The last time the file's inode was modified. [*]</td>
</tr>
<tr>
<td>C:</td>
<td>The last time the file's inode was modified displayed in a human-readable format.</td>
</tr>
<tr>
<td>D</td>
<td>Device number for the file. This number uniquely identifies the device (disk partition, for example) on which the file resides.</td>
</tr>
<tr>
<td>I</td>
<td>Inode number for the file. The inode number uniquely identifies a file on a particular device.</td>
</tr>
<tr>
<td>F</td>
<td>A string of the form <code>device:inode</code>. This string uniquely identifies a file anywhere on the system.</td>
</tr>
<tr>
<td>N</td>
<td>Number of hard links to the file.</td>
</tr>
<tr>
<td>P</td>
<td>The file's permissions, shown in octal, without a leading 0.</td>
</tr>
<tr>
<td>U</td>
<td>Numeric user ID of the file's owner.</td>
</tr>
<tr>
<td>U:</td>
<td>Username of the file's owner.</td>
</tr>
<tr>
<td>G</td>
<td>Numeric group ID of the file's group.</td>
</tr>
<tr>
<td>G:</td>
<td>Name of the file's group.</td>
</tr>
<tr>
<td>Z</td>
<td>Number of bytes in the file.</td>
</tr>
</tbody>
</table>

[*] Time measured in seconds from the epoch (usually the start of January 1, 1970).

You can use only one of these operators in a given test, and it must appear as the last operator in a multiple-operator sequence. Because 0 can be a valid response from some of these operators (for instance, the number of bytes in a file might be 0), most return `1` on failure instead of the 0 that the logical operators return on failure. The one exception is `F`, which returns a colon if it cannot determine the device and inode for the file.

When you want to use one of these operators outside of a control structure expression, you can use the `filetest` builtin to evaluate a file test and report the result:

```
tcsh $ filetest -z if_1
0
```

```
tcsh $ filetest -F if_1
2051:12694
```
The `goto` statement has the following syntax:

```
goto
label
```

A `goto` builtin transfers control to the statement beginning with `label`. The following script fragment demonstrates the use of `goto`:

```
tcsh $ cat goto_1
#!/bin/tcsh
#
# test for 2 arguments
#
if ($#argv == 2) goto goodargs
echo "Usage: goto_1 arg1 arg2"
exit 1
goodargs:
...
```

The `goto_1` script displays a usage message (page 440) when it is called with more or fewer than two arguments.

Interrupt Handling

The `onintr` statement transfers control when you interrupt a shell script. The format of an `onintr` statement is

```
onintr
label
```

When you press the interrupt key during execution of a shell script, the shell transfers control to the statement beginning with `label`. This statement allows you to terminate a script gracefully when it is interrupted. You can use it to ensure that when you interrupt a shell script, the script removes temporary files before returning control to the
parent shell.

The following script demonstrates `onintr`. It loops continuously until you press the interrupt key, at which time it displays a message and returns control to the shell:

```bash
tcsh $ cat onintr_1
#!/bin/tcsh
# demonstration of onintr
onintr close
while ( 1 )
    echo "Program is running."
    sleep 2
end
close:
echo "End of program."
```

If a script creates temporary files, you can use `onintr` to remove them.

```bash
close:
rm -f /tmp/$$
```

The ambiguous file reference `/tmp/$$*` matches all files in `/tmp` that begin with the PID number of the current shell. Refer to page 478 for a description of this technique for naming temporary files.

The `if...then...else` control structure has three forms. The first form, an extension of the simple `if` structure, executes more complex `commands` or a series of `commands` if `expression` is `true`. This form is still a one-way branch.

```bash
if ( expression ) then
    commands
endif
```

The second form is a two-way branch. If `expression` is `true`, the first set of `commands` is executed. If it is `false`, the set of `commands` following `else` is executed.
The third form is similar to the `if...then...elif` structure (page 442). It performs tests until it finds an `expression` that is `true` and then executes the corresponding `commands`.

```plaintext
if (expression) then
  commands
else if (expression) then
  commands
else
  commands
endif
```

The following program assigns a value of 0, 1, 2, or 3 to the variable `class` based on the value of the first command line argument. The program declares the variable `class` at the beginning for clarity; you do not need to declare it before its first use. Also for clarity, the script assigns the value of the first command line argument to `number`.

```plaintext
tcsh $ cat if_else_1
#!/bin/tcsh
# routine to categorize the first command line argument
set class
set number = $argv[1]
#
if ($number < 0) then
  @ class = 0
else if (0 <= $number && $number < 100) then
  @ class = 1
else if (100 <= $number && $number < 200) then
```
@ class = 2 else @ class = 3 endif
#

```
    echo "The number $number is in class ${class}."
```

The first `if` statement tests whether `number` is less than 0. If it is, the script assigns 0 to `class` and transfers control to the statement following `endif`. If it is not, the second `if` tests whether the number is between 0 and 100. The `&&` is the Boolean AND operator, yielding a value of `true` if the expression on each side is `true`. If the number is between 0 and 100, 1 is assigned to `class` and control is transferred to the statement following `endif`. A similar test determines whether the number is between 100 and 200. If it is not, the final `else` assigns 3 to `class`. The `endif` closes the `if` control structure. The final statement uses braces (`{ }`) to isolate the variable `class` from the following period. The braces isolate the period for clarity; the shell does not consider a punctuation mark to be part of a variable name. The braces would be required if you wanted other characters to follow immediately after the variable.

```
foreach

    loop-index
    (    argument-list
    )
    commands
end
```

This structure loops through `commands`. The first time through the loop, the structure assigns the value of the first argument in `argument-list` to `loop-index`. When control reaches the `end` statement, the shell assigns the value of the next argument from `argument-list` to `loop-index` and executes the commands again. The shell repeats this procedure until it exhausts `argument-list`.

The following `tcsh` script uses a `foreach` structure to loop through the files in the working directory containing a specified string of characters in their filename and to change the string. For example, you can use it to change the string `memo` in filenames to `letter`. The filenames `memo.1`, `dailymemo`, and `memories` would change to `letter.1`, `dailyletter`, and `letterries`.

This script requires two arguments: the string to be changed (the old string) and the new string. The `argument-list` of the `foreach` structure uses an ambiguous file reference to loop through all filenames that contain the first argument. For each filename that matches the ambiguous file reference, the `mv` utility changes the filename. The `echo` and `sed` commands appear within back ticks (`'`) that indicate command substitution: Executing the commands within the back ticks replaces the back ticks and everything between them. Refer to "Command Substitution" on page 329 for more information. The `sed` utility (page 563) substitutes the first argument for the second argument in the filename. The `$1` and `$2` are abbreviated forms of `Sargv[1]` and `Sargv[2]`. 
#!/bin/tcsh

# Usage:        ren arg1 arg2
# changes the string arg1 in the names of files
# in the working directory into the string arg2
if ($#argv != 2) goto usage
foreach i ( *$1* )
    mv $i 'echo $i | sed -n s/$1/$2/p'
end
exit 0

usage:

echo "Usage: ren arg1 arg2"
exit 1
optional

The next script uses a `foreach` loop to assign the command line arguments to the elements of an array named `buffer`:

```bash
# The next script uses a `foreach` loop to assign the command line arguments to the elements of an array named `buffer`:

tcsh $ cat foreach_1

#!/bin/tcsh
#
# routine to zero-fill argv to 20 arguments
#
set buffer = (0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0)
set count = 1
#
if ($#argv > 20) goto toomany
#
foreach argument ($argv[*])
    set buffer[$count] = $argument
    @ count++
end
#
# REPLACE command ON THE NEXT LINE WITH
# THE PROGRAM YOU WANT TO CALL.
exec command $buffer[*]
#
# toomany:
echo "Too many arguments given."
echo "Usage: foreach_1 [up to 20 arguments]"
exit 1
```

The `foreach_1` script calls another program named `command` with a command line guaranteed to contain 20 arguments. If `foreach_1` is called with fewer than 20 arguments, it fills the command line with zeros to complete the 20 arguments for `command`. Providing more than 20 arguments causes it to
display a usage message and exit with an error status of 1.

The **foreach** structure loops through the commands one time for each command line argument. Each time through the loop, **foreach** assigns the value of the next argument from the command line to the variable **argument**. Then the script assigns each of these values to an element of the array **buffer**. The variable **count** maintains the index for the **buffer** array. A postfix operator increments the **count** variable using `@(@count++)`. The **exec** builtin (**bash** and **tcsh**; page 491) calls **command** so that a new process is not initiated. (Once **command** is called, the process running this routine is no longer needed so a new process is not required.)

```bash
while
```

The syntax of the **while** structure is

```bash
   while (expression) commands end
```

This structure continues to loop through **commands** while **expression** is **true**. If **expression** is **false** the first time it is evaluated, the structure never executes **commands**.

```bash
tcsh $ cat while_1
#!/bin/tcsh

# Demonstration of a while control structure.
# This routine sums the numbers between 1 and n,
# with n being the first argument on the command # line.

set limit = $argv[1]
set index = 1
set sum = 0

while ($index <= $limit)
    @ sum += $index
    @ index++
end
```
#

echo "The sum is $sum"

This program computes the sum of all integers up to and including $n$, where $n$ is the first argument on the command line. The += operator assigns the value of $sum + index$ to $sum$.

**break** and **continue**

You can interrupt a **foreach** or **while** structure with a **break** or **continue** statement. These statements execute the remaining commands on the line before they transfer control. The **break** statement transfers control to the statement after the **end** statement, terminating execution of the loop. The **continue** statement transfers control to the **end** statement, which continues execution of the loop.

**switch**

The **switch** structure is analogous to the **bash** **case** structure (page 459):

```
switch (test-string)
  case pattern:
    commands
    breaksw
  case pattern:
    commands
    breaksw
  ...
  default:
    commands
    breaksw
endsw
```

The **breaksw** statement transfers control to the statement following the **endsw** statement. If you omit a **breaksw**, control falls through to the next command. You can use any of the special characters listed in **Table 11-2** on page
control falls through to the next command. You can use any of the special characters listed in Table 11-2 on page 462 within pattern except the pipe symbol (|).

tcsh $ cat switch_1
#!/bin/tcsh

# Demonstration of a switch control structure.
# This routine tests the first command line argument
# for yes or no in any combination of uppercase and
# lowercase letters.
#
# test that argv[1] exists
if ($#argv != 1) then
    echo "Usage: switch_1 [yes|no]"
    exit 1
else
# argv[1] exists, set up switch based on its value
    switch ($argv[1])
    # case of YES
        case [yY][eE][sS]:
            echo "Argument one is yes."
            breaksw
        #
        # case of NO
        case [nN][oO]:
            echo "Argument one is no."
            breaksw
        #
        # default case
default:

echo "Argument one is neither yes nor no."

breaksw

endsw

endif

Builtins

Builtins are commands that are part of (built into) the shell. When you give a simple filename as a command, the shell first checks whether it is the name of a builtin. If it is, the shell executes it as part of the calling process; the shell does not fork a new process to execute the builtin. The shell does not need to search the directory structure for builtin programs because they are immediately available to the shell.

If the simple filename you give as a command is not a builtin, the shell searches the directory structure for the program you want, using the PATH variable as a guide. When it finds the program the shell forks a new process to execute the program.

Although they are not listed in Table 9-10, the control structure keywords (if, foreach, endsw, and so on) are builtins. The table describes many of the tcsh builtins, some of which are also built into other shells.

<table>
<thead>
<tr>
<th>Builtin</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>% job</td>
<td>A synonym for the \fg builtin. The job is the job number of the job you want to bring to the foreground (page 272).</td>
</tr>
<tr>
<td>% job &amp;</td>
<td>A synonym for the \bg builtin. The job is the number of the job you want to put in the background (page 273).</td>
</tr>
<tr>
<td>@</td>
<td>Similar to the set builtin but evaluates numeric expressions. Refer to &quot;Numeric Variables&quot; on page 358.</td>
</tr>
<tr>
<td>alias</td>
<td>Creates and displays aliases; \bash uses a different syntax than \tcsh. Refer to &quot;Aliases&quot; on page 347.</td>
</tr>
<tr>
<td>alloc</td>
<td>Displays a report of the amount of free and used memory.</td>
</tr>
<tr>
<td>bg</td>
<td>Moves a suspended job into the background (page 273).</td>
</tr>
<tr>
<td>bindkey</td>
<td>Controls the mapping of keys to the \tcsh command line editor commands.</td>
</tr>
<tr>
<td>bindkey</td>
<td>Without any arguments, bindkey lists all key bindings (page 353).</td>
</tr>
<tr>
<td>bindkey \hl</td>
<td>Lists all available editor commands along with a short description of each.</td>
</tr>
<tr>
<td>bindkey \he</td>
<td>Puts the command line editor in emacs mode (page 353).</td>
</tr>
<tr>
<td>bindkey \hv</td>
<td>Puts the command line editor in vi(m) mode (page 353).</td>
</tr>
<tr>
<td>bindkey \hl \hl key command</td>
<td>Attaches the editor command command to the key key.</td>
</tr>
<tr>
<td>bindkey \lb \hl key command</td>
<td>Similar to the previous form but allows you to specify control keys by using the form C\hl x (where x is the character you type while you press the CONTROL key), specify meta key sequences as M\hl x (on most keyboards used with Linux, the ALT key is the</td>
</tr>
</tbody>
</table>
meta key), and specify function keys as F-x.

**bindkey**  \[ key command \]  
Binds the key **key** to the command **command**. Here the **command** is not an editor command but either a shell builtin or an executable program.

**bindkey**  \[ key string \]  
Whenever you type **key**, **string** is substituted.

**builtins**  
Displays a list of all builtins.

**cd** or **chdir**  
Changes working directories (page 82).

**dirs**  
Displays the directory stack (page 274).

**echo**  
Displays its arguments. You can prevent **echo** from displaying a RETURN at the end of a line by using the \[n\] option (see "Reading User Input" on page 361) or by using a trailing \[c\] (see "read: Accepts User Input: Accepts User Input" on page 487). The **echo** builtin is similar to the **echo** utility (page 647).

**eval**  
Scans and evaluates the command line. When you put **eval** in front of a command, the command is scanned twice by the shell before it is executed. This feature is useful with a command that is generated by command or variable substitution. Because of the order in which the shell processes a command line, it is sometimes necessary to repeat the scan to achieve the desired result (page 318).

**exec**  
Overlays the program currently being executed with another program in the same shell. The original program is lost. Refer to "exec: Executes a Command: Executes a Command" on page 491 for more information; also refer to **source** (page 380).

**exit**  
Exits from a TC Shell. When you follow it with a numeric argument, **tcsh** returns that number as the exit status (page 479).

**fg**  
Moves a job into the foreground (page 271).

**filetest**  
Takes one of the file inquiry operators followed by one or more filenames and applies the operator to each filename (page 370). Returns the results as a space-separated list.

**glob**  
Like **echo**, but does not display SPACEs between its arguments and does not follow its display with a NEWLINE.

**hashstat**  
Reports on the efficiency of **tcsh**’s hash mechanism. The hash mechanism speeds the process of searching through the directories in your search path. See also **rehash** (page 380) and **unhash** (page 381).

**history**  
Displays a list of recent commands (page 344).

**jobs**  
Displays a list of jobs (suspended commands and those running in the background).

**kill**  
Terminates a job or process (page 497).

**limit**  
Limits the computer resources that the current process and any processes it creates can use. You can put limits on the number of seconds of CPU time the process can use, the size of files that the process can create, and so forth.

**log**  
Immediately produces the report that the **watch** shell variable (page 365) would normally produce every 10 minutes.

**login**  
Logs in a user. Can be followed by a username.

**logout**  
Ends a session if you are using your original (login) shell.

**ls**  \[F\]  
Similar to **ls** \[F\] but faster. (This builtin is the characters **ls** \[F\] without any SPACEs.)

**nice**  
Lowers the processing priority of a command or a shell. It is useful if you want to run a command that makes large demands on the system and you do not need the output right away. If you are Superuser, you can use **nice** to raise the priority of a command. Refer to page 734 for more information on the **nice** builtin and the **nice** utility, which is available from **bash**.

**nohup**  
Allows you to log out without terminating processes running in the background. Some systems are set up to do this automatically. Refer to page 736 for information on the
Buildin | Function
--- | ---
nohup | builtin and the nohup utility, which is available from bash.
notify | Causes the shell to notify you immediately when the status of one of your jobs changes (page 271).
onintr | Controls what action an interrupt causes within a script (page 371). See "trap: Catches a Signal" on page 493 for information on the equivalent command in bash.
popd | Removes a directory from the directory stack (page 274).
printenv | Displays all environment variable names and values.
pushd | Changes the working directory and places the new directory at the top of the directory stack (page 274).
rehash | Re-creates the internal tables used by the hash mechanism. Whenever a new instance of tcsh is invoked, the hash mechanism creates a sorted list of all available commands based on the value of path. After you add a command to a directory in path, use rehash to re-create the sorted list of commands. If you do not, tcsh may not be able to find the new command. Also refer to hashstat (page 379) and unhash (page 381).
repeat | Takes two arguments—a count and simple command (no pipes or lists of commands)—and repeats the command the number of times specified by the count.
sched | Executes a command at a specified time. For example, the following command causes the shell to print the message Dental appointment. at 10 AM:

tcsh $ sched 10:00 echo "Dental appointment."

Without any arguments, sched prints the list of scheduled commands. When the time to execute a scheduled command arrives, tcsh executes the command just before it displays a prompt.

set | Declares, initializes, and displays local variables (page 355).
setenv | Declares, initializes, and displays environment variables (page 355).
shift | Analogous to the bash shift builtin (page 483). Without an argument, shift promotes the indexes of the argv array. You can use it with an argument of an array name to perform the same operation on that array.
source | Executes the shell script given as its argument: source does not fork another process. It is similar to the bash . (dot) builtin (page 259). The source builtin expects a TC Shell script so no leading #! is required in the script. The current shell executes source so that the script can contain commands, such as set, that affect the current shell. After you make changes to your .tcshrc or .login file, you can use source to execute it from the shell and thereby put the changes into effect without logging off and on. You can nest source builtins.
stop | Stops a job or process that is running in the background. The stop builtin accepts multiple arguments.
suspend | Stops the current shell and puts it in the background. It is similar to the suspend key, which stops jobs running in the foreground.
time | Executes the command that you give it as an argument. It displays a summary of time-related information about the executed command, according to the time shell variable (page 364). Without an argument, time displays the times for the current shell and its children.
umask | Identifies or changes the access permissions that are assigned to files you create (page 810).
unalias | Removes an alias (page 347).
unhash | Turns off the hash mechanism. See also hashstat (page 379) and rehash (page...
Builtins

- **unset**
  - Removes a variable declaration (page 355).

- **unlimit**
  - Removes limits (page 379) on the current process.

- **unsetenv**
  - Removes an environment variable declaration (page 355).

- **wait**
  - Causes the shell to wait for all child processes to terminate. When you give a `wait` command in response to a shell prompt, `tcsh` does not display a prompt until all background processes have finished execution. If you interrupt it with the interrupt key, `wait` displays a list of outstanding processes before `tcsh` displays a prompt.

- **where**
  - When given the name of a command as an argument, locates all occurrences of the command and, for each, tells you whether it is an alias, a builtin, or an executable program in your path.

- **which**
  - Similar to `where` but reports on only the command that would be executed, not all occurrences. This builtin is much faster than the Linux `which` utility and knows about aliases and builtins.

Chapter Summary

Like the Bourne Again Shell, the TC Shell is both a command interpreter and a programming language. The TC Shell, which is based on the C Shell that was developed at the University of California at Berkeley, includes popular features such as history, alias, and job control.

You may prefer to use `tcsh` as a command interpreter, especially if you are familiar with the C Shell. You can use `chsh` to change your login shell to `tcsh`. However, running `tcsh` as your interactive shell does not cause `tcsh` to run shell scripts; they will continue to be run by `bash` unless you explicitly specify another shell on the first line of the script or specify the script name as an argument to `tcsh`. Specifying the shell on the first line of a shell script ensures the behavior you expect.

If you are familiar with `bash`, you will notice some differences between the two shells. For instance, the syntax you use to assign a value to a variable differs and `tcsh` allows SPACEs around the equal sign. Both numeric and nonnumeric variables are created and given values using the `set` builtin. The `@` builtin can evaluate numeric expressions for assignment to numeric variables.

### setenv

Because there is no `export` builtin in `tcsh`, you must use the `setenv` builtin to create an environment (global) variable. You can also assign a value to the variable with the `setenv` command. The command `unset` removes both local and environment variables, whereas the command `unsetenv` removes only environment variables.

### Aliases

The syntax of the `tcsh alias` builtin is slightly different from that of `alias` in `bash`. Unlike `bash`, the `tcsh` aliases permit you to substitute command line arguments using the history mechanism syntax.

Most other `tcsh` features, such as history, word completion, and command line editing, closely resemble their `bash` counterparts. The syntax of the `tcsh` control structures is slightly different but provides functionality equivalent to that found in `bash`. 
Globbing

The term *globbing*, a carryover from the original Bourne Shell, refers to the matching of strings containing special characters (such as * and ?) to filenames. If *tcsh* is unable to generate a list of filenames matching a globbing pattern, it displays an error message. This behavior contrasts with that of *bash*, which simply leaves the pattern alone.

Standard input and standard output can be redirected in *tcsh*, but there is no straightforward way to redirect them independently. Doing so requires the creation of a subshell that redirects standard output to a file while making standard error available to the parent process.

**Exercises**

1. Assume that you are working with the following history list:

   37 mail alex
   38 cd /home/jenny/correspondence/business/cheese_co
   39 less letter.0321
   40 vim letter.0321
   41 cp letter.0321 letter.0325
   42 grep hansen letter.0325
   43 vim letter.0325
   44 lpr letter*
   45 cd ../milk_co
   46 pwd
   47 vim wilson.0321 wilson.0329

   Using the history mechanism, give commands to
   
   a. Send mail to Alex.
   
   b. Use *vim* to edit a file named *wilson.0329*.
   
   c. Send *wilson.0329* to the printer.
   
   d. Send both *wilson.0321* and *wilson.0329* to the printer.
2. **How can you display the aliases currently in effect?** Write an alias named **homedots** that lists the names (only) of all invisible files in your home directory.

3. **How can you prevent a command from sending output to the terminal when you start it in the background?** What can you do if you start a command in the foreground and later decide that you want it to run in the background?

4. **What statement can you put in your ~/.tcshrc file to prevent accidentally overwriting a file when you redirect output?** How can you override this feature?

5. **Assume that the working directory contains the following files:**

   - adams.ltr.03
   - adams.brief
   - adams.ltr.07
   - abelson.09
   - abelson.brief
   - anthony.073
   - anthony.brief
   - azevedo.99

   What happens if you press TAB after typing the following commands?
   
   a. less adams.l
   b. cat a
   c. ls ant
   d. file az

   What happens if you press CONTROL-D after typing the following commands?
   
   e. ls ab
   f. less a

6. **Write an alias named **backup** that takes a filename as an argument and creates a copy of that file with the same name and a filename extension of .bak.**
7. Write an alias named `qmake` (quiet make) that runs `make` with both standard output and standard error redirected to the file named `make.log`. The command `qmake` should accept the same options and arguments as `make`.

8. How can you make `tcsh` always display the pathname of the working directory as part of its prompt?

Advanced Exercises

9. What lines do you need to change in the Bourne Again Shell script `command_menu` (page 462) to turn it into a TC Shell script? Make the changes and verify that the new script works.

10. Users often find `rm` (and even `rm -i`) too unforgiving because it removes files irrevocably. Create an alias named `delete` that moves files specified by its argument(s) into the `~/.trash` directory. Create a second alias named `undelete` that moves a file from the `~/.trash` directory into the working directory. Put the following line in your `~/.logout` file to remove any files that you deleted during the login session:

```
/bin/rm -f $HOME/.trash/* >& /dev/null
```

Explain what could be different if the following line were put in your `~/.logout` file instead:

```
rm $HOME/.trash/*
```

11. Modify the `foreach_1` script (page 374) so that it takes the command to `exec` as an argument.

12. Rewrite the program `while_1` (page 375) so that it runs faster. Use the `time` builtin to verify the improvement in execution time.

13. Write your own version of `find` named `myfind` that writes output to the file `findout` but without the clutter of error messages, such as those generated when you do not have permission to search a directory. The `myfind` command should accept the same options and arguments as `find`. Can you think of a situation in which `myfind` does not work as desired?

14. When the `foreach_1` script (page 374) is supplied with 20 or fewer arguments, why are the commands following `toomany` not executed? (Why is there no `exit` command?)

System Calls 417

Source Code Management 420

CVS: Concurrent Versions System 420

With its rich set of languages and development tools, the Linux operating system provides an outstanding environment for programming. C is one of the most popular system programming languages to use in conjunction with Linux, in part because the operating system itself is written mostly in C. Using C, programmers can easily access system services using function libraries and system calls. In addition, a variety of helpful tools can facilitate the development and maintenance of programs.

This chapter explains how to compile and link C programs. It introduces the GNU gdb debugger and tools that provide feedback about memory, disk, and CPU resources. It also covers some of the most useful software development tools: the make utility and CVS. The make utility helps you keep track of which program modules have been updated and helps to ensure that you use the latest versions of all program modules when you compile a program. CVS (Concurrent Versions System) is a source code management system that tracks the versions of files involved in a project.
A major reason that the Linux system provides an excellent C programming environment is that C programs can easily access the services of the operating system. The system calls—the routines that make operating system services available to programmers—can be called from C programs. These system calls provide such services as creating files, reading from and writing to files, collecting information about files, and sending signals to processes. When you write a C program, you can use system calls in the same way you use ordinary C program modules, or functions, that you have written. For more information refer to “System Calls” on page 417.

Several libraries of functions have been developed to support programming in C. The libraries are collections of related functions that you can use just as you use your own functions and the system calls. Many of the library functions access basic operating system services through the system calls, providing the services in ways that are more suited to typical programming tasks. Other library functions, such as the math library functions, serve special purposes.

This chapter describes the processes of writing and compiling C programs. However, it will not teach you to program in C.

Checking Your Compiler

The C compiler in common use on Linux is GNU gcc (www.gnu.org/software/gcc/gcc.html), which comes as part of most distributions. Give the following command to see if you have access to the gcc compiler:

$ gcc --version
bash: gcc: command not found

If you get a response other than version information, either the compiler is not installed or your PATH variable does not contain the necessary pathname (usually gcc is installed in /usr/bin). If you get version information from the gcc command, the GNU C compiler is installed.

Next make sure that the compiler is functioning. As a simple test, create a file named Makefile with the following lines. The line that starts with gcc must be indented by using a TAB, not SPACEs.

$ cat Makefile

morning: morning.c

TAB gcc -o morning morning.c

Now create a source file named morning.c with the following lines:

$ cat morning.c
#include <stdio.h>

int main(int argc, char** argv) {

printf("Good Morning\n");

return 0;
}

Compile the file with the command **make morning**. When it compiles successfully, run the program by giving the command **morning** or **./morning**. When you get output from this program, you know that you have a working C compiler:

```
$ make morning

gcc -o morning morning.c

$ morning

Good Morning
```

**A C Programming Example**

You must use an editor, such as **emacs** or **vim**, to create or change a C program. The name of the C program file must end in **.c**. Entering the source code for a program is similar to typing a memo or shell script. Although **emacs** and **vim** "know" that you are editing a C program, many editors do not know whether your file is a C program, a shell script, or an ordinary text document. You are responsible for making the contents of the file syntactically suitable for the C compiler to process.

Figure 10-1 illustrates the structure of a simple C program named **tabs.c**. The first two lines of the program are comments that describe what the program does. The string */* identifies the beginning of the comment, and the string */* identifies the end of the comment; the C compiler ignores all the characters between them. Because a comment can span two or more lines, the */* at the end of the first line and the */* at the beginning of the second line are not necessary but are included for clarity. As the comment explains, the program reads standard input, converts TAB characters into the appropriate number of spaces, and writes the transformed input to standard output. Like many Linux utilities, this program is a filter.

Figure 10-1. A simple C program: tabs.c (The line numbers are not part of the source code.)
Following the comments at the top of `tabs.c` are preprocessor directives, which are instructions for the C preprocessor. During the initial phase of compilation the C preprocessor expands these directives, making the program ready for the later stages of the compilation process. Preprocessor directives begin with the pound sign (#) and may optionally be preceded by SPACE and TAB characters.

Symbolic constants

You can use the `#define` preprocessor directive to define symbolic constants and macros. Symbolic constants are names that you can use in a program in place of constant values. For example, `tabs.c` uses a `#define` preprocessor directive to associate the symbolic constant `TABSIZE` with the constant 8. `TABSIZE` is used in the program in place of the constant 8 as the distance between TAB stops. By convention the names of symbolic constants consist of all uppercase letters.
By defining symbolic names for constant values you can make a program easier to read and easier to modify. If you later decide to change a constant, you need to change only the preprocessor directive rather than the value everywhere it occurs in the program. If you replace the `#define` directive for `TABSIZE` in Figure 10-1 with the following directive, the program will place TAB stops every four columns rather than every eight:

```c
#define TABSIZE 4
```

A symbolic constant, which is a type of `macro`, maps a symbolic name to `replacement text`. Macros are handy when the replacement text is needed at multiple points throughout the source code or when the definition of the macro is subject to change. The process of substituting the replacement text for the symbolic name is called `macro expansion`.

**Macros**

You can also use `#define` directives to define macros with arguments. Use of such a macro resembles a function call. Unlike C functions, however, macros are replaced with C code prior to compilation into object files.

The `NEXTTAB` macro computes the distance to the next TAB stop, given the current column position `curcol`:

```c
#define NEXTTAB(curcol) (TABSIZE - ((curcol) % TABSIZE))
```

This definition uses the macro `TABSIZE`, whose definition must appear prior to `NEXTTAB` in the source code. The macro `NEXTTAB` could be used in `tabs.c` to assign a value to `retval` in the function `findstop`:

```c
retval = NEXTTAB(*col);
```

**Headers (include files)**

When modules of a program use several macro definitions, the definitions are typically collected together in a single file called a `header file` or an `include file`. Although the C compiler does not place constraints on the names of header files, by convention they end in `.h`. The name of the header file is listed in an `#include` preprocessor directive in each program source file that uses any of the macros. The program in Figure 10-1 uses `getchar` and `putchar`, which are macros defined in `stdio.h`. The `stdio.h` header file defines a variety of general-purpose macros and is used by many C library functions.

The angle brackets (`<` and `>`) that surround `stdio.h` in `tabs.c` instruct the C preprocessor to look for the header file in a standard list of directories (such as `/usr/include`). To include a header file from another directory, enclose its pathname between double quotation marks. You can specify an absolute pathname within the double quotation marks or you can give a relative pathname. If you give a relative pathname, searching begins with the working directory and then moves to the same directories that are searched when the header file is surrounded by angle brackets. By convention header files that you supply are surrounded by double quotation marks.

You can also specify directories to be searched for header files by using the `-l` option to the C compiler. Assume that you want to compile the program `deriv.c`, which contains the following preprocessor directive:
#include "eqns.h"

If the header file `eqns.h` is located in the subdirectory `myincludes`, you can compile `deriv.c` with the `-I` option to tell the C preprocessor to look for the file `eqns.h` there:

```bash
$ gcc -I./myincludes deriv.c
```

When the C preprocessor encounters the `#include` directive in the `deriv.c` file, it will look for `eqns.h` in the `myincludes` subdirectory of the working directory.

**tip: Use relative pathnames for include files**

Using absolute pathnames for include files does not work if the location of the header file within the filesystem changes. Using relative pathnames for header files works as long as the location of the header file relative to the working directory remains the same. Relative pathnames also work with the `-I` option on the `gcc` command line and allow header files to be moved.

**Function prototype**

Preceding the definition of the function `main` is a *function prototype*. This declaration tells the compiler what type a function returns, how many arguments a function expects, and what the types of those arguments are. In `tabs.c` the prototype for the function `findstop` informs the compiler that `findstop` returns type `int` and that it expects a single argument of type `pointer to int`:

```c
int findstop(int *);
```

Once the compiler has seen this declaration, it can detect and flag inconsistencies in the definition and the uses of the function. As an example, suppose that the reference to `findstop` in `tabs.c` was replaced with the following statement:

```c
inc = findstop();
```

The prototype for `findstop` would cause the compiler to detect a missing argument and issue an error message. You could then easily fix the problem. When a function is present in a separate source file or is defined after it is referenced in a source file (as `findstop` is in the example), the function prototype helps the compiler check that the function is being called properly. Without the prototype, the compiler would not issue an error message and the problem might manifest itself as unexpected behavior during execution. At this late point, finding the bug might be difficult and time-consuming.

**Functions**

Although you can call most C functions anything you want, each program must have exactly one function named `main`. The function `main` is the control module: A program begins execution with the function `main`, which
The function `main` is the control module: A program begins execution with the function `main`, which typically calls other functions, which in turn may call still other functions, and so forth. By putting different operations into separate functions, you can make a program easier to read and maintain. For example, the program in Figure 10-1 uses the function `findstop` to compute the distance to the next `TAB` stop. Although the few statements of `findstop` could easily have been included in the `main` function, isolating them in a separate function draws attention to a key computation.

Functions can make both development and maintenance of the program more efficient. By putting a frequently used code segment into a function, you avoid entering the same code into the program over and over again. When you later want to make changes to the code, you need change it only once.

If a program is long and includes several functions, you may want to split it into two or more files. Regardless of its size, you may want to place logically distinct parts of a program in separate files. A C program can be split into any number of different files; however, each function must be wholly contained within a single file.

**tip: Use a header file for multiple source files**

When you are creating a program that takes advantage of multiple source files, put `#define` preprocessor directives into a header file and use an include statement with the name of the header file in any source file that uses the directives.

### Compiling and Linking a C Program

To compile `tabs.c` and create an executable file named `a.out`, give the following command:

```
$ gcc tabs.c
```

The `gcc` utility calls the C preprocessor, the C compiler, the assembler, and the linker. Figure 10-2 shows these four components of the compilation process. The C preprocessor expands macro definitions and includes header files. The compilation phase creates assembly language code corresponding to the instructions in the source file. Then the assembler creates machine-readable object code. One object file is created for each source file. Each object file has the same name as the source file, except that the `.c` extension is replaced with a `.o`. The preceding example creates a single object file named `tabs.o`. After successfully completing all phases of the compilation process for a program, the C compiler creates the executable file and then removes any `.o` files.

*Figure 10-2. The compilation process*
During the final phase of the compilation process, the linker searches specified libraries for functions the program uses and combines object modules for those functions with the program’s object modules. By default, the C compiler links the standard C library `libc.so` (usually found in `/lib`), which contains functions that handle input and output and provides many other general-purpose capabilities. If you want the linker to search other libraries, you must use the `l` (lowercase "l") option to specify the libraries on the command line. Unlike most options to Linux system utilities, the `l` option does not come before all filenames on the command line but usually appears after the filenames of all modules that it applies to. In the next example, the C compiler searches the math library `libm.so` (usually found in `/lib`):

```
$ gcc calc.c -lm
```

The `l` option uses abbreviations for library names, appending the letter following `l` to `lib` and adding a `.so` or `.a` extension. The `m` in the example stands for `libm.so`.

Using the same naming mechanism, you can have a graphics library named `libgraphics.a`, which can be linked with the following command:

```
$ gcc pgm.c -lgraphics
```

When you use this convention to name libraries, `gcc` knows to search for them in `/usr/lib` and `/lib`. You can have `gcc` also search other directories by using the `L` option:

```
$ gcc pgm.c -L. -L/usr/X11R6/lib -lgraphics
```
The preceding command causes `gcc` to search for the library file `libgraphics.a` in the working directory and in `/usr/X11R6/lib` before searching `/usr/lib` and `/lib`.

As the last step of the compilation process, the linker creates an executable file named `a.out` unless you specify a different filename with the `-o` option. Object files are deleted after the executable is created.

ELF format

You may occasionally encounter references to the `a.out` format, an old UNIX binary format. Linux uses the Executable and Linking Format (ELF) for binaries; recent versions of `gcc` produce this format—not the `a.out` format, in spite of the filename. Use the `file` utility (page 653) to determine the format of the executable that `gcc` generates:

```
$ file a.out
a.out: ELF 32-bit LSB executable, Intel 80386, version 1 (SYSV), for GNU/Linux 2.2.5,
       dynamically linked (uses shared libs), not stripped
```

In the next example, the `-O3` option causes `gcc` to use the C compiler optimizer. The optimizer makes object code more efficient so that the executable program runs more quickly. Optimization has many facets, including locating frequently used variables and taking advantage of processor-specific features. The number after the `-O` indicates the level of optimization, where a higher number specifies more optimization. See the `gcc info` page for specifics. The following example also shows that the `.o` files are not present after `a.out` is created:

```
$ ls
acctspay.c  acctsrec.c  ledger.c
$ gcc -O3 ledger.c acctspay.c acctsrec.c
$ ls
a.out  acctspay.c  acctsrec.c  ledger.c
```

You can use the executable `a.out` in the same way you use shell scripts and other programs: by typing its name on the command line. The program in Figure 10-1 on page 390 expects to read from standard input, so once you have created the executable `a.out` you can use a command such as the following to run it:

```
$ ./a.out < mymemo
```

If you want to save the `a.out` file, you should change the name to a more descriptive one. Otherwise, you might
If you want to save the a.out file, you should change the name to a more descriptive one. Otherwise, you might accidentally overwrite it during a later compilation:

$ mv a.out accounting

To save yourself the trouble of renaming an a.out file, you can specify the name of the executable file when you use gcc. The -o option causes the C compiler to give the executable the name you specify rather than a.out. In the next example, the executable is named accounting:

$ gcc -o accounting ledger.c acctspay.c acctsrec.c

If accounting does not require arguments, you can run it with the following command:

$ accounting

You can suppress the linking phase of compilation by using the -c option with the gcc command. The -c option does not treat unresolved external references as errors; this capability enables you to compile and debug the syntax of the modules of a program as you create them. Once you have compiled and debugged all the modules, you can run gcc again with the object files as arguments to produce an executable program. In the next example, gcc produces three object files but no executable:

$ gcc -c ledger.c acctspay.c acctsrec.c
$ ls
acctspay.c acctspay.o acctsrec.c acctsrec.o ledger.c ledger.o

If you then run gcc again and name the object files on the command line, gcc will produce the executable. Because it recognizes the filename extension .o, the C compiler knows that the files need only to be linked. You can also include both .c and .o files on a single command line:

$ gcc -o accounting ledger.o acctspay.c acctsrec.o

The C compiler recognizes that the .c file needs to be preprocessed and compiled, whereas the .o files do not. The C compiler also accepts assembly language files ending in .s and assembles and links them. This feature makes it easy to modify and recompile a program.

You can use separate files to divide a project into functional groups. For instance, you might put graphics routines in one file, string functions in another, and database calls in a third. Multiple files can enable several engineers to work on the same project concurrently and can speed up compilation. If all functions are in one file and you make a change, the compiler must recompile all functions in the file. Thus the entire program will be recompiled, which may take considerable time even if you made only a small change. When you use separate files, only the file that you change must be recompiled. For large programs with many source files (for example, the C compiler or emacs), the time lost by recompiling one huge file for every small change would be enormous. For more
information, refer to "make: Keeps a Set of Programs Current" on page 399.

**tip: What not to name a program**

Do not name a program `test` or any other name of a builtin or other executable on the local system. If you do, you will likely execute the builtin or other program instead of the program you intend to run. Use `which` (page 61) to determine which program you will run when you give a command.
Using Shared Libraries

Most modern operating systems use shared libraries, also called dynamic libraries. These libraries are not linked into a program at compile time but rather are loaded when the program starts (or later in some cases). The names of files housing shared libraries have filename extensions of .so (shared object); for example, `libc.so`. Usually `libaaa.so` is a symbolic link to `libaaa.so.x`, where `x` is a small number representing the version of the library. Many of these libraries are kept in `/usr/lib`: A typical Linux installation has more than 300 shared libraries in `/usr/lib` and more than 30 in `/usr/X11R6/lib`. Applications can have their own shared libraries. For example, the `gcc` compiler might keep its libraries in `/usr/lib/gcc-lib/i386-redhat-linux/3.4.0`.

Archived libraries

In contrast to shared libraries are the older, statically linked libraries (with a .a filename extension), also called archived libraries. Archived libraries are added to the executable file during the last (link) phase of compilation. This addition can make a program run slightly faster the first time it is run, albeit at the expense of program maintainability and size. Taken together, the combined size of several executables that use a shared library and the size of the shared library are smaller than the combined size of the same executables with static libraries. When a running program has already loaded a dynamic library, a second program that requires the same dynamic library starts slightly faster.

Reducing memory usage and increasing maintainability are the primary reasons for using shared object libraries; they have largely replaced statically linked libraries as the library type of choice. Consider what happens when you discover an error in a library. With a static library, you need to relink every program that uses the library once the library has been fixed and recompiled. With a dynamic library, you need to fix and recompile only the library itself.

Shared object libraries also make dynamic loading of program libraries on the fly possible (for example, perl, python, and tcl extensions and modules). The Apache (HTTP) Web server specifies modules in the `httpd.conf` file and loads them as needed.

Ldd

The `l`dd (list dynamic dependencies) utility tells you which shared libraries a program needs. The following example shows that `cp` uses libacl, the Access Control Lists library; libc, the C library; libattr, the Extended Attributes library; and ld-linux, the runtime linker:

```
$ ldd /bin/cp

libacl.so.1 => /lib/libacl.so.1 (0x40026000)
libc.so.6 => /lib/i686/libc.so.6 (0x42000000)
libattr.so.1 => /lib/libattr.so.1 (0x4002d000)
/lib/ld-linux.so.2 => /lib/ld-linux.so.2 (0x40000000)
```

Running `l`dd on `/usr/bin/gnome-session` (a program that starts a graphical GNOME session) lists 59 libraries from `/usr/lib`, `/usr/X11R6/lib`, and `/lib`.

The program that does the dynamic runtime linking, `ld-linux.so`, always looks in `/usr/lib` for libraries. The other directories that `ld` searches vary depending on how `ld` is set up. You can add directories for `ld` to look in by
specifying a search path at compile (actually link) time, using the \texttt{-r} option followed by a colon-separated list of directories (do not put a \texttt{SPACE} after \texttt{-r}). Use only absolute pathnames in the search path. Although you use this option on the \texttt{gcc} command line, it is passed to the linker (\texttt{ld}). The \texttt{gnome-session} desktop manager was likely linked with a command such as the following:

\begin{verbatim}
gcc \
flags \
-o gnome-session \
objects \
-r/lib:/usr/X11R6/lib \
libraries
\end{verbatim}

This command line allows \texttt{ld.so} (and \texttt{ldd}) to search /lib and /usr/X11R6/lib in addition to the standard /usr/lib for the libraries needed by the executable.

The compiler needs to see the shared libraries at link time to make sure that the needed functions and procedures are present as promised by the header (.h) files. Use the \texttt{-L} option to tell the compile-time linker to look in the directory \texttt{mylib} for shared or static libraries: \texttt{-L mylib}. Unlike the search path, \texttt{-L} can use relative pathnames such as \texttt{../lib} handy when a program builds its own shared library. The library can be in one location at build time (\texttt{L}) but in another location at runtime after it is installed (\texttt{r path}). The \texttt{SPACE} after \texttt{L} is optional and is usually omitted; \texttt{r} must not be followed by a \texttt{SPACE}. You can repeat the \texttt{L} and the \texttt{r} options multiple times on the link line.

\section*{Fixing Broken Binaries}

The command line search path is a fairly new idea. The search path was traditionally created by using the \texttt{LD_LIBRARY_PATH} and, more recently, the \texttt{LD_RUN_PATH} environment variables. These variables have the same format as \texttt{PATH} (page 284).

The directories in \texttt{LD_LIBRARY_PATH} are normally searched before the usual library locations. Newer Linux releases extend the function of \texttt{LD_LIBRARY_PATH} to specify directories to be searched either before or after the normal locations. See the \texttt{ld man} page for details. The \texttt{LD_RUN_PATH} variable behaves similarly to \texttt{LD_LIBRARY_PATH}. If you use \texttt{-r}, however, \texttt{LD_LIBRARY_PATH} supersedes anything in \texttt{LD_RUN_PATH}.

The use of \texttt{LD_LIBRARY_PATH} brings up several problems. Because only one environment variable exists, it must be shared among all programs. If two programs have the same name for a library or use different, incompatible versions of the same library, only the first will be found. As a result one of the programs will not run or worse will not run correctly.

\textbf{security: LD_LIBRARY_PATH}

Under certain circumstances a malicious user can create a Trojan horse named \texttt{libc.so} and place it in a directory that is searched before /usr/lib (any directory in \texttt{LD_LIBRARY_PATH}, which appears before /usr/lib). The fake \texttt{libc} will then be used instead of the real \texttt{libc}.

\section*{Wrappers}

\texttt{LD_LIBRARY_PATH} still has its place in the scripts, called \textit{wrappers}, that are used to fix broken binaries. Suppose that the broken binary \texttt{bb} uses the shared library \texttt{libbb.so}, which you want to put in /opt/bb/lib and not in /usr/lib, as the \texttt{bb} programmer requested. The command \texttt{ldd bb} will tell you which libraries are missing. Not a problem: Rename \texttt{bb} to \texttt{bb.broken}, and create a /bin/sh wrapper named \texttt{bb}.
#!/bin/sh

LD_LIBRARY_PATH=/opt/bb/lib
export LD_LIBRARY_PATH
exec bb.broken "$@

(Using $@ rather than $* preserves SPACEs in the parameters; see page 482.) A wrapper can also allow you to install programs in arbitrary locations.

Creating Shared Libraries

Building a dynamically loadable shared library is not a trivial matter: It involves using reentrant function calls, defining a library entrance routine, and performing other tasks. When you want to create a shared object library, you must at a minimum compile the source files with the fPIC (position-independent code) option to gcc and link the resulting object files into the lib xx .so file using the shared x options to the linker (for example, ld -shared -x -o libmylib.so *.o). The best resource for investigating shared library construction and usage is existing code on the Internet. For example, you can look at the source files for zlib (www.gzip.org/zlib).

C++

C++ files have special needs, and libraries (shared or not) often have to be made by the compiler rather than ld or ar. Shared libraries can depend on other shared libraries and have their own search paths. If you set LD_LIBRARY_PATH, add the i flag to the link phase when compiling to ignore the current LD_LIBRARY_PATH or you may have unexpected results. Ideally, you would not have LD_LIBRARY_PATH set on a global level but would use it only in wrappers as needed.
**make:** Keeps a Set of Programs Current

**tip:** This section covers the GNU `make` program

This section describes the GNU `make` program. Other `make` tools (BSN `make`, GNUStep `make`, Borland `make`, and so on) are available as well as similar tools such as `ant` (the Apache build tool). Makefiles created for GNU `make` are often incompatible with other `make` tools, which can be problematic if you are trying to compile code targeted for another platform.

In a large program with many source and header files, the files typically depend on one another in complex ways. When you change a file that other files depend on, you must recompile all dependent files. For example, you might have several source files, all of which use a single header file. When you change the header file, you must recompile each of the source files. The header file might depend on other header files, and so forth. Figure 10-3 shows a simple example of dependency relationships. Each arrow in this figure points from a file to another file that depends on it.

**Figure 10-3. Dependency graph for the target form**

![Dependency graph for the target form](image)

When you are working on a large program, it can be difficult, time-consuming, and tedious to determine which modules need to be recompiled because of their dependency relationships. The `make` utility automates this process.

**Dependency lines: target files and prerequisite files**

At its simplest, `make` looks at dependency lines in a file named `Makefile` or `makefile` in the working directory. The dependency lines indicate relationships among files, specifying a target file that depends on one or more
dependency lines indicate relationships among files, specifying a target file that depends on one or more prerequisite files. If you have modified any of the prerequisite files more recently than their target file, make updates the target file based on construction commands that follow the dependency line. The make utility normally stops if it encounters an error during the construction process.

The file containing the updating information for the make utility is called a makefile. (See page 388 for a trivial example.) A simple makefile has the following syntax:

\[
\text{target: prerequisite-list} \\
\text{TAB construction-commands}
\]

The dependency line consists of the target and the prerequisite-list, separated by a colon. Each construction-commands line (you may have more than one) must start with a TAB and must follow the dependency line. Long lines can be continued with a BACKSLASH (\) as the last character on the line.

The target is the name of the file that depends on the files in the prerequisite-list. The construction-commands are regular shell commands that construct (usually compile and/or link) the target file. The make utility executes the construction-commands when the modification time of one or more files in the prerequisite-list is more recent than that of the target file.

The following example shows the dependency line and construction commands for the file named form in Figure 10-3. The form file depends on the prerequisites size.o and length.o. An appropriate gcc command constructs the target:

form: size.o length.o

TAB gcc -o form size.o length.o

Each of the prerequisites on one dependency line can be a target on another dependency line. For example, both size.o and length.o are targets on other dependency lines. Although the example in Figure 10-3 is simple, the nesting of dependency specifications can create a complex hierarchy that dictates relationships among many files.

The following makefile (named Makefile) corresponds to the complete dependency structure shown in Figure 10-3. The executable file form depends on two object files, and the object files each depend on their respective source files and a header file, form.h. In turn, form.h depends on two other header files.

$ cat Makefile

form: size.o length.o
    gcc -o form size.o length.o

size.o: size.c form.h
    gcc -c size.c

length.o: length.c form.h
    gcc -c length.c
form.h: num.h table.h

    cat num.h table.h > form.h

Although the last line would not normally be seen in a makefile, it illustrates the fact that you can put any shell command on a construction line. Because the shell processes makefiles, the command line should be one that you could enter in response to a shell prompt.

The following command builds the default target form if any of its prerequisites are more recent than their corresponding targets or if any of the targets do not exist:

$ make

Thus, if the file form has been deleted, make will rebuild it, regardless of the modification dates of its prerequisite files. The first target in a makefile is the default and is built when you call make without any arguments.

If you want make to rebuild a target other than the first in the makefile, you must provide that target as an argument to make. The following command rebuilds only form.h if it does not exist or if its prerequisites are more recent than the target:

$ make form.h

Implied Dependencies

You can rely on implied dependencies and construction commands to facilitate the job of writing a makefile. For instance, if you do not include a dependency line for an object file, make assumes that it depends on a compiler or assembler source code file. Thus, if a prerequisite for a target file is xxx.o and no dependency line identifies xxx.o as a target, make looks at the extension to determine how to build the .o file. If it finds an appropriate source file, make provides a default construction command line that calls the proper compiler or the assembler to create the object file. Table 10-1 lists some filename extensions that make recognizes and the type of file that corresponds to each suffix.

<table>
<thead>
<tr>
<th>Filename with extension</th>
<th>Type of file</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename.c</td>
<td>C programming language source code</td>
</tr>
<tr>
<td>filename.C, filename.cc, filename.cxx, filename.c++, filename.cpp</td>
<td>C++ programming language source code</td>
</tr>
<tr>
<td>filename.f</td>
<td>Fortran programming language source code</td>
</tr>
<tr>

<tr>
<td>filename.l</td>
<td>f lex, lex lexical analyzer generator source code</td>
</tr>
<tr>
<td>filename.o</td>
<td>Object module</td>
</tr>
<tr>
<td>filename.s</td>
<td>Assembler code</td>
</tr>
</tbody>
</table>
C and C++ are traditional programming languages that are available with many Linux distributions. The **bison** and **flex** tools create command languages.

In the next example a makefile keeps the file named **compute** up-to-date. The **make** utility ignores any line that begins with a pound sign (#). Thus the first three lines of the following makefile are comment lines. The first dependency line shows that **compute** depends on two object files: **compute.o** and **calc.o**. The corresponding construction line gives the command **make** needs to produce **compute**. The second dependency line shows that **compute.o** depends not only on its C source file but also on the **compute.h** header file. The construction line for **compute.o** uses the C compiler optimizer (\texttt{O3} option). The third set of dependency and construction lines is not required. In their absence, **make** infers that **calc.o** depends on **calc.c** and produces the command line needed for the compilation:

```
$ cat Makefile
#
# Makefile for compute
#
compute: compute.o calc.o
   gcc -o compute compute.o calc.o

compute.o: compute.c compute.h
   gcc -c -O3 compute.c

calc.o: calc.c
   gcc -c calc.c

clean:
   rm *.o *core* *~
```

There are no prerequisites for **clean**, the last target. This target is commonly used to get rid of extraneous files that may be out-of-date or no longer needed, such as .o files.

Following are some sample executions of **make** based on the previous makefile. As the **ls** command shows, **compute.o**, **calc.o**, and **compute** are not up-to-date. Consequently the **make** command runs the construction
commands that re-create them.

$ ls -ltr

total 22
-rw-rw---- 1 alex pubs 311 Jun 21 15:56 makefile
-rw-rw---- 1 alex pubs 354 Jun 21 16:02 calc.o
-rwxrw--- 1 alex pubs 6337 Jun 21 16:04 compute
-rw-rw---- 1 alex pubs 49 Jun 21 16:04 compute.h
-rw-rw---- 1 alex pubs 880 Jun 21 16:04 compute.o
-rw-rw---- 1 alex pubs 780 Jun 21 18:20 compute.c
-rw-rw---- 1 alex pubs 179 Jun 21 18:20 calc.c

$ make

gcc -c -O3 compute.c

gcc -c calc.c

gcc -o compute compute.o calc.o

If you run make once and then run it again without making any changes to the prerequisite files, make indicates that the program is up-to-date and does not execute any commands:

$ make

make: 'compute' is up to date.

touch

The next example uses the touch utility to change the modification time of a prerequisite file. This simulation shows what happens when you alter the file. The make utility executes only the commands necessary to bring the out-of-date targets up-to-date:

$ touch calc.c

$ make
gcc -c calc.c

gcc -o compute compute.o calc.o

In the next example, touch changes the modification time of compute.h. The make utility re-creates compute.o because it depends on compute.h and re-creates the executable because it depends on compute.o:

```
$ touch compute.h
$ make
gcc -c -O3 compute.c
gcc -o compute compute.o calc.o
```

If you want to see what make would do if you ran it, run make with the `n` (no execute) option. The `n` option shows the commands that make would execute but it does not execute them.

```
$ make -n
make: 'compute' is up to date.
$ touch *.c
$ make -n
gcc -c -O3 compute.c
```

As these examples illustrate, touch is useful when you want to fool make either into recompiling programs or into not recompiling them. You can use touch to update the modification times of all source files so that make considers nothing to be up-to-date; make will then recompile everything. Alternatively, you can use touch or the `t` option to make to touch all relevant files; make then considers everything to be up-to-date. Using touch in this manner is useful if the modification times of files have changed yet the files remain up-to-date (as can happen when you copy a set of files from one directory to another).

The following example uses make `n` several times to see what make would do if you gave a make command. The first command shows that the target, compute, is up-to-date. Next touch makes the modification dates on all the *.c files more recent than their targets and make `n` shows what make would do if you called it without the `n` option. The make `t` command then brings all the targets up-to-date. The final make `n` confirms that compute is up-to-date.

```
$ make -n
make: 'compute' is up to date.
$ touch *.c
$ make -n
gcc -c -O3 compute.c
```

```
gcc -c calc.c
```
gcc -o compute compute.o calc.o

$ make -t
touch compute.o
touch calc.o
touch compute

$ make -n
make: 'compute' is up to date.

The `j` (jobs) option performs a number of tasks in parallel; the numeric argument to `j` specifies the number of jobs or processes. Most `make` tasks hit the disk first and then the CPU, resulting in CPU usage dropping between compiles. On a multiprocessor system, you can reduce CPU usage by using `make j n`, where `n` is the number of CPUs plus 1. Running tasks in parallel can significantly reduce the build time for a large project.

Once you are satisfied with the program you have created, you can use the makefile to remove extraneous files. It is helpful to keep intermediate files around while you are writing and debugging a program so that you need to rebuild only the ones that change. When you will not be working on the program for a while, you can release the disk space. Using a `clean` target in a makefile means that you do not have to remember all the little pieces that can safely be deleted. The next example simply removes all object (.o) files:

$ make clean

rn *.o
optional: Macros

The `make` utility's macro facility enables you to create and use macros within a makefile. The syntax of a macro definition is

```
ID = list
```

Replace `ID` with an identifying name, and replace `list` with a list of filenames. After this macro definition, `$ID` represents `list` in the makefile.

With a macro you can compile a program with any of several C compilers, making only a minor change to the makefile. By using the `CC` macro and replacing all occurrences of `gcc` in the makefile on page 402 with `$CC`, for example, you need to assign a value only to `CC` to use the compiler of your choice:

```
$ cat Makefile
#
# Makefile for compute
#
CC=gcc

compute: compute.o calc.o
    $(CC) -o compute compute.o calc.o

compute.o: compute.c compute.h
    $(CC) -c -O3 compute.c

calc.o: calc.c
    $(CC) -c calc.c

clean:
    rm *.o
```
This example assumes that the compiler/loader flags are the same across compilers/loaders. In a more complex situation, you need to create macros for these flags or use the default values. Several commercial, high-performance compilers are available for Linux. You could specify the compiler from the Portland Group, pgcc, by replacing the CC=gcc assignment with CC=pgcc. If you do not assign a value to the CC macro, it defaults to gcc under Linux. The CC macro invokes the C compiler with only the options that you specify.

Several other macro definitions are commonly used. The CFLAGS macro sends arguments to the C compiler, LDFLAGS sends arguments to the linker (ld, or gcc -o), and CPPFLAGS sends arguments to the C preprocessor and programs that use it, including gcc. The COMPILE.c macro expands to $(CC) $(CFLAGS) $(CPPFLAGS). The LINK.c macro expands to $(CC) $(CFLAGS) $(CPPFLAGS) $(LDFLAGS).

By default make invokes the C compiler without any options (except the -c option when it is appropriate to compile but not to link a file). You can use the CFLAGS macro definition to cause make to call the C compiler with specific options. Replace options with the options you want to use:

```
CFLAGS =
options
```

The following makefile uses macros as well as implied dependencies and constructions:

```
# makefile: report, print, printf, printh
#
CC=gcc
CFLAGS = -O3
# comment out the two lines above and uncomment the
# two below when you are using the Portland Group's compiler
#CC=pgcc
#CFLAGS = -fast
FILES = in.c out.c ratio.c process.c tally.c
OBJECTS = in.o out.o ratio.o process.o tally.o
HEADERS = names.h companies.h conventions.h

report: $(OBJECTS)
```
$(LINK.c) -o report $(OBJECTS)

ratio.o: $(HEADERS)

process.o: $(HEADERS)

tally.o: $(HEADERS)

print:
    pr $(FILES) $(HEADERS) | lpr

printf:
    pr $(FILES) | lpr

printh:
    pr $(HEADERS) | lpr

Following the comment lines in this example, the makefile uses the CFLAGS macro to cause make always to use the optimizer (O3 option) when it invokes the C compiler as the result of an implied construction. (The CC and CFLAGS definitions for the pgcc C compiler perform the same functions when they are uncommented and you are working with pgcc, except that you use fast with pgcc where you use O3 with gcc.) A construction line in a makefile overrides the corresponding implied construction line, if one exists. If you want to apply a macro to a construction command, you must include the macro in that command; see OBJECTS in the construction command for the report target. Following CFLAGS, the makefile defines the FILES, OBJECTS, and HEADERS macros. Each of these macros defines a list of files.

The first dependency line in the preceding example shows that report depends on the list of files that OBJECTS defines. The corresponding construction line links the OBJECTS and creates an executable file named report.

The next three dependency lines show that three object files depend on the list of files that HEADERS defines. Because there are no construction lines, make looks for a source code file corresponding to each object file and compiles it. These three dependency lines ensure that the object files are recompiled if any header files change.
Finally the **LINK.c** macro is invoked to link the executable file. If you specify any **LDFLAGS**, they are used in this step.

You can combine several targets on one dependency line, so these three dependency lines could have been combined into one line as follows:

```
ratio.o process.o tally.o: $(HEADERS)
```

The three final dependency lines in the preceding example send source and header files to the printer. They have nothing to do with compiling the **report** file. None of these targets (**print**, **printf**, and **printh**) depends on anything. When you call one of these targets from the command line, **make** executes the construction line following it. The following command prints all the source files that **FILES** defines:

```
$ make printf
```

You can override macros in a makefile by specifying them on the command line. The following command adds debugging symbols to all object files:

```
$ make CFLAGS=-g ...
```
Debugging C Programs

The C compiler is liberal about the kinds of constructs it allows in programs. In keeping with the UNIX philosophy that "no news is good news" and that the user knows what is best, gcc, like many other Linux utilities, accepts almost anything that is logically possible according to the definition of the language. Although this approach gives the programmer a great deal of flexibility and control, it can make debugging difficult.

Figure 10-4 on page 409 shows badtabs.c, a flawed version of the tabs.c program discussed earlier. It contains some errors and does not run properly. This section uses this program to illustrate some debugging techniques.
In the following example, **badtabs.c** is compiled and then run with input from the **testtabs** file. Inspection of the output shows that the TAB character has not been replaced with the proper number of SPACEs:

```
$ gcc -o badtabs badtabs.c
$ cat testtabs
abcTABxyz
$ badtabs < testtabs
abc   xyz
```

One way to debug a C program is to insert print statements at critical points throughout the source code. To learn more about the behavior of **badtabs.c** when it runs, you can replace the contents of the `switch` statement with

```c
case '\t': /* c is a tab */
    fprintf(stderr, "before call to findstop, posn is %d
", posn);
    inc = findstop(&posn);
    fprintf(stderr, "after call to findstop, posn is %d
", posn);
    for( ; inc > 0; inc-- )
        putchar(' ');
    break;

case '\n': /* c is a newline */
    fprintf(stderr, "got a newline
" );
    putchar(c);
    posn = 0;
    break;

default: /* c is anything else */
    fprintf(stderr, "got another character
" );
    putchar(c);
    posn++;
    break;
```
The `fprintf` statements in this code send their messages to standard error. Thus, if you redirect standard output of this program, it will not be interspersed with the output sent to standard error. The next example demonstrates the operation of this program on the input file `testtabs`:

```
$ gcc -o badtabs badtabs.c
$ badtabs < testtabs > testspaces
```

got another character

got another character

got another character

before call to findstop, posn is 3

after call to findstop, posn is 3

got another character

got another character

got another character

got a newline

$ cat testspaces

abcTABxyz

The `fprintf` statements provide additional information about the execution of `tabs.c`. The value of the variable `posn` is not incremented in `findstop`, as it should be. This clue might be enough to lead you to the bug in the program. If not, you might attempt to "corner" the offending code by inserting print statements in `findstop`.

For simple programs or when you have an idea of what is wrong with a program, adding `print` statements that trace the execution of the code can often help you solve the problem quickly. A better strategy may be to take advantage of the tools that Linux provides to help you debug programs.

**gcc: Compiler Warning Options**

The `gcc` compiler includes many of the features of `lint`, the classic C program verifier, and then some. (The `lint` utility is not available under Linux; use `splint` [secure programming lint; www.splint.org] instead.) The `gcc` compiler can identify many C program constructs that pose potential problems, even for programs that conform to the syntax rules of the language. For instance, you can request that the compiler report whether a variable is declared but not used, a comment is not properly terminated, or a function returns a type not permitted in older versions of C. Options that enable this stricter compiler behavior all begin with the uppercase letter `W` (Warning).

Among the `W` options is a class of warnings that typically result from programmer carelessness or inexperience (see Table 10-2). The constructs that generate these warnings are generally easy to fix and easy to avoid.
Table 10-2. gcc `W' options

<table>
<thead>
<tr>
<th>Option</th>
<th>Reports an error when</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Wimplicit</code></td>
<td>A function or parameter is not explicitly declared</td>
</tr>
<tr>
<td><code>Wreturn-type</code></td>
<td>A function that is not void does not return a value or the type of a function defaults to int</td>
</tr>
<tr>
<td><code>Wunused</code></td>
<td>A variable is declared but not used</td>
</tr>
<tr>
<td><code>Wcomment</code></td>
<td>The characters / *, which normally begin a comment, occur within a comment</td>
</tr>
<tr>
<td><code>Wformat</code></td>
<td>Certain input/output statements contain format specifications that do not match the arguments</td>
</tr>
</tbody>
</table>

The `Wall` option displays warnings about all the errors listed in Table 10-2, along with other, similar errors.

The program `badtabs.c` is syntactically correct: It compiles without generating an error. However, if you compile it (`c` causes `gcc` to compile but not to link) with the `Wall` option, `gcc` displays several problems. (Warning messages do not stop the program from compiling, whereas error messages do do.)

```
$ gcc -c -Wall badtabs.c
badtabs.c:47: warning: '/*' within comment
badtabs.c:11: warning: return-type defaults to 'int'
badtabs.c: In function 'main':
badtabs.c:34: warning: control reaches end of non-void function
badtabs.c: In function 'findstop':
badtabs.c:40: warning: unused variable 'colindex'
badtabs.c:49: warning: control reaches end of non-void function
```

The first warning message references line 47. Inspection of the code for `badtabs.c` around that line reveals a comment that is not properly terminated. The compiler sees the string `/*` in the following line as the beginning of a comment:

```
/* increment argument (current column position) to next tabstop */
```

However, because the characters `*` and `/` at the end of the line are separated by a SPACE, they do not signify the end of the comment to the compiler. Instead the compiler interprets all the statements—including the statement that increments the argument—through the string `*/` at the very end of the `findstop` function as part of the comment.

Compiling with the `Wall` option can be very helpful when you are debugging a program. After you remove the `SPACE` between the characters `*` and `/`, `badtabs` produces the correct output.

The next few paragraphs discuss the remaining warning messages. Although most do not cause problems in the execution of `badtabs`, you can generally improve a program by rewriting those parts of the code that produce such warnings.

Because the definition of the function `main` does not include an explicit type, the compiler assumes type `int`, the default. This results in the warning message referencing line 11 in `badtabs.c`, the top of the function `main`. An
additional warning is given when the compiler encounters the end of the function `main` (line 34) without seeing a value returned.

If a program runs successfully, by convention it should return a zero value; if no value is returned, the exit code is undefined. Although many C programs do not return a value, this oversight can cause problems when the program is executed. When you add the following statement at the end of the function `main` in `badtabs.c`, the warning referencing line 34 disappears:

```c
return 0;
```

Line 40 of `badtabs.c` contains the definition for the local variable `colindex` in the function `findstop`. The warning message referencing that line occurs because the `colindex` variable is never used. Removing its declaration eliminates the warning message.

The final warning message, referencing line 49, results from the improperly terminated comment discussed earlier. The compiler issues the warning message because it never sees a `return` statement in `findstop`. (The compiler ignores commented text.) Because the function `findstop` returns type `int`, the compiler expects a `return` statement before reaching the end of the function. The warning disappears when the comment is properly terminated.

Many other `W` options are available with the `gcc` compiler. The ones not covered in the `Wall` class often deal with portability differences; modifying the code causing these warnings may not be appropriate. The warnings usually result from programs that are written in different C dialects as well as from constructs that may not work well with other (especially older) C compilers. The `pedantic-errors` option turns warnings into errors, causing a build to fail if it contains items that would generate warnings. To learn more about these and other warning options, refer to the `gcc info` page.

**Symbolic Debugger**

Many debuggers are available to tackle problems that evade the simpler debugging methods such as print statements and compiler warning options. These debuggers include `gdb`, `kdbg`, `xxgdb` `mxgdb`, `ddd`, and `ups`, which are available from the Web (refer to Appendix B). All are high-level symbolic debuggers that enable you to analyze the execution of a program in terms of C language statements. The debuggers also provide a lower-level view for analyzing the execution of a program in terms of the machine instructions. Except for `gdb`, each of these debuggers provides a GUI.

A debugger enables you to monitor and control the execution of a program. You can step through a program line by line while you examine the state of the execution environment.

**Core dumps**

A debugger also allows you to examine `core` files. (Core files are named `core`.) When a serious error occurs during the execution of a program, the operating system can create a core file containing information about the state of the program and the system when the error occurred. This file comprises a dump of the computer's memory (it was previously called `core memory`—hence the term `core dump`) that was being used by the program. To conserve disk space, your system may not save core files automatically. You can use the `ulimit` built-in to enable core files to be saved. If you are running `bash`, the following command allows core files of unlimited size to be saved to disk:

```
$ ulimit -c unlimited
```
The operating system advises you when it dumps core. You can use a symbolic debugger to read information from the core file to identify the line in the program where the error occurred, to check the values of variables at that point, and so forth. Because core files tend to be large and take up disk space, be sure to remove these files when you no longer need them.

**gdb: Symbolic Debugger**

The following examples demonstrate the use of the GNU gdb debugger. Other symbolic debuggers offer a different interface but operate in a similar manner. To make full use of a symbolic debugger with a program, you must compile the program with the `g` option, which causes gcc to generate additional information that the debugger uses. This information includes a symbol table—a list of variable names used in the program and their associated values. Without the symbol table information, the debugger cannot display the values and types of variables. If a program is compiled without the `g` option, gdb cannot identify source code lines by number, as many gdb commands require.

**tip: Always use `g`**

It can be helpful always to use the `g` option even when you are releasing software. Including debugging symbols makes a binary a bit bigger. Debugging symbols do not make a program run more slowly, but they do make it much easier to find problems identified by users.

**tip: Avoid using optimization flags with the debugger**

Limit the optimization flags to `O` or `O2` when you compile a program for debugging. Because debugging and optimizing inherently have different goals, it may be best to avoid combining the two operations.

The following example uses the `g` option when creating the executable file `tabs` from the C program `tabs.c`, discussed at the beginning of this chapter:

```
$ gcc -g tabs.c -o tabs
```

**tip: Optimization should work**

Turning optimization off completely can sometimes eliminate errors. Eliminating errors in this way should not be seen as a permanent solution, however. When optimization is not enabled, the compiler may automatically initialize variables and perform certain other checks for you, resulting in more stable code. Correct code should work correctly when compiled with at least `O` and almost certainly `O2`. The `O3` setting often includes experimental optimizations so it may not generate correct code in all cases.

Input for `tabs` is contained in the file `testtabs`, which consists of a single line:

```
$ cat testtabs
xyzTABabc
```
You cannot specify the input file to `tabs` when you first call the debugger. Specify the input file once you have called the debugger and started execution with the `run` command.

To run the debugger on the sample executable, give the name of the executable file on the command line when you run `gdb`. You will see some introductory statements about `gdb`, followed by the `gdb` prompt `[gdb]`. At this point the debugger is ready to accept commands. The `list` command displays the first ten lines of source code. A subsequent `list` command displays the next ten lines of source code.

```
$ gdb tabs
GNU gdb 4.18
...
(gdb) list
4       #include <stdio.h>
5       #define TABSIZE 8
6
7       /* prototype for function findstop */
8       int findstop(int *);
9
10      int main()
11      {
12      int c;    /* character read from stdin */
13      int posn = 0;  /* column position of character */
14      int inc;    /* column increment to tab stop */
15
16      while ((c = getchar()) != EOF)
17              switch(c)
18                      {
19                      case '\t':    /* c is a tab */
20                              inc = findstop(&posn);
21                              for( ; inc > 0; inc-- )
```

```
One of the most important features of a debugger is its ability to run a program in a controlled environment. You can stop the program from running whenever you want. While it is stopped, you can check the state of an argument or variable. For example, you can give the `break` command a source code line number, an actual memory address, or a function name as an argument. The following command tells `gdb` to stop the process whenever the function `findstop` is called:

```
(gdb) break findstop
Breakpoint 1 at 0x804849f: file tabs.c, line 41.
```

The debugger acknowledges the request by displaying the breakpoint number, the hexadecimal memory address of the breakpoint, and the corresponding source code line number (41). The debugger numbers breakpoints in ascending order as you create them, starting with 1.

After setting a breakpoint you can issue a `run` command to start execution of `tabs` under the control of the debugger. The `run` command syntax allows you to use angle brackets to redirect input and output (just as the shells do). In the following example, the `testtabs` file is specified as input. When the process stops (at the breakpoint), you can use the `print` command to check the value of `*col`. The `backtrace` (or `bt`) command displays the function stack. The example shows that the currently active function has been assigned the number 0. The function that called `findstop` (main) has been assigned the number 1:

```
(gdb) run < testtabs
Starting program: /home/mark/book/10/tabs < testtabs

Breakpoint 1, findstop (col=0xbfffffc70) at tabs.c:41
41      retval = (TABSIZE - (*col % TABSIZE));
(gdb) print *col
$1 = 3
(gdb) backtrace
#0  findstop (col=0xbfffffc70) at tabs.c:41
#1  0x804843a in main () at tabs.c:20
```
You can examine anything in the current scope: variables and arguments in the active function as well as globals. In the next example, the request to examine the value of the variable \texttt{posn} at breakpoint 1 results in an error. The error is generated because the variable \texttt{posn} is defined locally in the function \texttt{main}, not in the function \texttt{findstop}:

\begin{verbatim}
(gdb)

No symbol "posn" in current context.
\end{verbatim}

The \texttt{up} command changes the active function to the caller of the currently active function. Because \texttt{main} calls the function \texttt{findstop}, the function \texttt{main} becomes the active function when the \texttt{up} command is given. (The \texttt{down} command does the inverse.) The \texttt{up} command may be given an integer argument specifying the number of levels in the function stack to backtrack, with \texttt{up 1} having the same meaning as \texttt{up}. (You can use the \texttt{backtrace} command to determine the argument to use with \texttt{up}.)

\begin{verbatim}
(gdb) up
1 0x804843a in main () at tabs.c:20
20 inc = findstop(&posn);
(gdb) print posn
$2 = 3
(gdb) print *col
No symbol "col" in current context.
\end{verbatim}

The \texttt{cont} (continue) command causes the process to continue running from where it left off. The \texttt{testtabs} file contains only one line; the process finishes executing and the results appear on the screen. The debugger reports the exit code of the program. A \texttt{cont} command given after a program has finished executing reminds you that execution of the program is complete. The debugging session is then ended with a \texttt{quit} command.

\begin{verbatim}
(gdb) cont
Continuing.
abc     xyz
Program exited normally.
\end{verbatim}
The program is not being run.

(gdb) quit
$

The **gdb** debugger supports many commands that are designed to make debugging easier. Type **help** at the (gdb) prompt to get a list of the command classes available under **gdb**:

(gdb) help
List of classes of commands:

- aliases -- Aliases of other commands
- breakpoints -- Making program stop at certain points
- data -- Examining data
- files -- Specifying and examining files
- internals -- Maintenance commands
- obscure -- Obscure features
- running -- Running the program
- stack -- Examining the stack
- status -- Status inquiries
- support -- Support facilities
- tracepoints -- Tracing of program execution without stopping the program
- user-defined -- User-defined commands

Type "help" followed by a class name for a list of commands in that class.

Type "help" followed by command name for full documentation.

Command name abbreviations are allowed if unambiguous.

(gdb)

As explained in the instructions following the list, entering **help** followed by the name of a command class or
As explained in the instructions following the list, entering `help` followed by the name of a command class or command will display more information. The following lists the commands in the class **data:**

```
(gdb) help data
Examining data.

List of commands:

call -- Call a function in the program
delete display -- Cancel some expressions to be displayed when program stops
disable display -- Disable some expressions to be displayed when program stops
disassemble -- Disassemble a specified section of memory
display -- Print value of expression EXP each time the program stops
enable display -- Enable some expressions to be displayed when program stops
inspect -- Same as "print" command
output -- Like "print" but don't put in value history and don't print newline
print -- Print value of expression EXP
printf -- Printf "printf format string"
ptype -- Print definition of type TYPE
set -- Evaluate expression EXP and assign result to variable VAR
set variable -- Evaluate expression EXP and assign result to variable VAR
undisplay -- Cancel some expressions to be displayed when program stops
whatis -- Print data type of expression EXP
x -- Examine memory: x/FMT ADDRESS
```

Type "help" followed by command name for full documentation.
Command name abbreviations are allowed if unambiguous.

(gdb)
The following requests information on the command `whatis`, which takes a variable name or other expression as an argument:

(gdb) help whatis

Print data type of expression EXP.

**Graphical Symbolic Debuggers**

Several graphical interfaces to **gdb** exist. The **xxgdb** graphical version of **gdb** provides a number of windows, including a Source Listing window, a Command window that contains a set of commonly used commands, and a Display window for viewing the values of variables. The left mouse button selects commands from the Command window. You can click the desired line in the Source Listing window to set a breakpoint, and you can select variables by clicking them in the Source Listing window. Selecting a variable and clicking **print** in the Command window will display the value of the variable in the Display window. You can view lines of source code by scrolling (and resizing) the Source Listing window.

The GNU **ddd** debugger ([www.gnu.org/software/ddd](http://www.gnu.org/software/ddd)) also provides a GUI to **gdb**. Unlike **xxgdb**, **ddd** can graphically display complex C structures and the links between them. This display makes it easier to see errors in these structures. Otherwise, the **ddd** interface is very similar to that of **xxgdb**.

Unlike **xxgdb**, **ups** ([ups.sourceforge.net](http://ups.sourceforge.net)) was designed from the ground up to work as a graphical debugger; the graphical interface was not added after the debugger was complete. The resulting interface is simple yet powerful. For example, **ups** automatically displays the value of a variable when you click it and provides a built-in C interpreter that allows you to attach C code to the program you are debugging. Because this attached code has access to the variables and values in the program, you can use it to perform sophisticated checks, such as following and displaying the links in a complex **data structure** (page 870).
**Threads**

A *thread* is a single sequential flow of control within a process. Threads are the basis for multithreaded programs, which allow a single program to control concurrently running threads, each performing a different task. Multithreaded programs generally use *reentrant* code (code that multiple threads can use simultaneously) and are most valuable when run on multiple-CPU machines. Under Linux, multithreaded servers, such as NFS, can provide a cleaner interface and may be easier to write than multiple server processes. When applied judiciously, multithreading can also serve as a lower-overhead replacement for the traditional fork-exec idiom for spawning processes. See the FAQ at tldp.org/FAQ/Threads-FAQ.

**tip: Multiple threads are not always better**

If you write a multithreaded program with no clear goal or division of effort for a single-CPU system (for example, a parallel-server process), the resulting program will likely run more slowly than a nonthreaded program on the same system.
System Calls

Three fundamental responsibilities of the Linux kernel are to control processes, manage the filesystem, and operate peripheral devices. As a programmer you have access to these kernel operations through system calls and library functions. This section discusses system calls at a general level; a detailed treatment is beyond the scope of this book.

As the name implies, a system call instructs the system (kernel) to perform some work directly on your behalf. The request is a message that tells the kernel what work needs to be done and includes the necessary arguments. For example, a system call to open a file includes the name of the file. A library routine is indirect; it issues system calls for you. The advantages of a library routine are that it may insulate you from the low-level details of kernel operations and that it has been written carefully to make sure that it performs efficiently.

For example, it is straightforward to use the standard I/O library function `fprintf()` to send text to standard output or standard error. Without this function, you would need to issue several system calls to achieve the same result. The calls to the library routines `putchar()` and `getchar()` in Figure 10-1 on page 390 ultimately use the `write()` and `read()` system calls to perform the I/O operations.

**strace: Traces System Calls**

The `strace` utility is a debugging tool that displays a trace of all system calls made by a process or program. Because you do not need to recompile the program that you want to trace, you can use `strace` on binaries that you do not have source for.

System calls are events that take place at the interface (boundary) between user code and kernel code. Examining this boundary can help you isolate bugs, track down race conditions, and perform sanity checking. The Linux kernel does not fully cooperate with `strace`. See the `strace` home page (www.liacs.nl/~wichert/strace) for kernel patches that improve kernel cooperation with `strace`.

Controlling Processes

When you enter a command line at a shell prompt, the shell process calls the `fork` system call to create a copy of itself (spawn a child) and then uses an `exec` system call to overlay that copy in memory with a different program (the command you asked it to run). Table 10-3 lists system calls that affect processes.

<table>
<thead>
<tr>
<th>System call</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fork()</code></td>
<td>Creates a copy of a process</td>
</tr>
<tr>
<td><code>exec()</code></td>
<td>Overlays a program in memory with another</td>
</tr>
<tr>
<td><code>getpid()</code></td>
<td>Returns the PID number of the calling process</td>
</tr>
<tr>
<td><code>wait()</code></td>
<td>Causes the parent process to wait for the child to finish running before it resumes execution</td>
</tr>
<tr>
<td><code>exit()</code></td>
<td>Causes a process to exit</td>
</tr>
<tr>
<td><code>nice()</code></td>
<td>Changes the priority of a process</td>
</tr>
<tr>
<td><code>kill()</code></td>
<td>Sends a signal to a process</td>
</tr>
</tbody>
</table>

Accessing The Filesystem
Many operations take place when a program reads from or writes to a file. The program needs to know where the file is located; the filename must be converted to an inode number on the correct filesystem. Your access permissions must be checked not only for the file itself but also for all intervening directories in the path to the file. The file is not stored in one continuous piece on the disk so all disk blocks that contain pieces of the file must be located. The appropriate kernel device driver must be called to control the operation of the disk. Once the file has been found, the program may need to find a particular location within the file rather than working with it sequentially from beginning to end. Table 10-4 lists some of the most common system calls for filesystem operations.

### Table 10-4. System calls: filesystem

<table>
<thead>
<tr>
<th>System call</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>stat()</td>
<td>Gets status information from an inode, such as the inode number, the device on which it is located, owner and group information, and the size of the file</td>
</tr>
<tr>
<td>lseek()</td>
<td>Moves to a position in the file</td>
</tr>
<tr>
<td>creat( )</td>
<td>Creates a new file</td>
</tr>
<tr>
<td>open( )</td>
<td>Opens an existing file</td>
</tr>
<tr>
<td>read( )</td>
<td>Reads a file</td>
</tr>
<tr>
<td>write( )</td>
<td>Writes a file</td>
</tr>
<tr>
<td>close( )</td>
<td>Closes a file</td>
</tr>
<tr>
<td>unlink( )</td>
<td>Unlinks a file (deletes a name reference to the inode)</td>
</tr>
<tr>
<td>chmod( )</td>
<td>Changes file access permissions</td>
</tr>
<tr>
<td>chown( )</td>
<td>Changes file ownership</td>
</tr>
</tbody>
</table>

Access to peripheral devices on a Linux system is handled through the filesystem interface. Each peripheral device is represented by one or more special files, usually located under /dev. When you read or write to one of these special files, the kernel passes your requests to the appropriate kernel device driver. As a result you can use the standard system calls and library routines to interact with these devices; you do not need to learn a new set of specialized functions. This ability is one of the most powerful features of a Linux system because it allows users to use the same basic utilities on a wide range of devices.

The availability of standard system calls and library routines is the key to the portability of Linux tools. For example, as an applications programmer, you can rely on the read and write system calls working the same way on different versions of the Linux system and on different types of computers. The systems programmer who writes a device driver or ports the kernel to run on a new computer, however, must understand the details at their lowest level.
Source Code Management

When you work on a project involving many files that evolve over long periods of time, it can be difficult to keep track of the different versions of the files, particularly if several people are updating the files. This problem frequently occurs in large software development projects. Source code and documentation files change frequently as you fix bugs, enhance programs, and release new versions of the software. The task becomes even more complex when more than one version of each file is active. Frequently customers are using one version of a file while a newer version is being modified. You can easily lose track of the versions and accidentally undo changes or duplicate earlier work.

To help avoid these kinds of problems, Linux includes CVS (Concurrent Versions System; www.cvshome.org) for managing and tracking changes to files. Although CVS can be used on any file, it is most often used to manage source code and software documentation. CVS is based on RCS (GNU's Revision Control System) and is designed to control the concurrent access and modification of source files by multiple users.

A graphical front end to CVS named TkCVS (page 429) simplifies the use of CVS, especially if you do not use it frequently enough to memorize its many commands and options.

CVS controls who is allowed to update files. For each update, CVS records who made the changes and why the changes were made. Because CVS stores the most recent version of a file and the information needed to re-create all previous versions, it is possible to regenerate any version of a file.

A set of versions for several files may be grouped together to form a release. An entire release can be re-created from the change information stored with each file. Saving the changes for a file rather than saving a complete copy of the file generally conserves a lot of disk space, well in excess of the space required to store each update in the CVS files themselves.

This section provides an overview of CVS and TkCVS. See the CVS -RCS-HOW-TO Document for Linux for more information.

CVS: Concurrent Versions System

CVS treats collections of files as single units, making it easy to work on large projects and permitting multiple users to work on the same file. CVS also provides valuable self-documenting features for its utilities.

Built-In CVS Help

CVS uses a single utility, cvs, for all its functions. To display the instructions for getting help, use the --help option:

$ cvs --help

where cvs-options are -q, -n, etc.

(specify --help-options for a list of options)

where command is add, admin, etc.

(specify --help-commands for a list of commands)
or --help-synonyms for a list of command synonyms)
where command-options-and-arguments depend on the specific command
(specify -H followed by a command name for command-specific help)
Specify --help to receive this message

The Concurrent Versions System (CVS) is a tool for version control.
For CVS updates and additional information, see

the CVS home page at http://www.cvshome.org/ or Pascal Molli's CVS
site at http://www.loria.fr/~molli/cvs-index.html

To get help with a cvs command, use the `--help` option followed by the name of the utility. The following example shows help for the `log` command:

$ cvs --help log

Usage: cvs log [-lRhtNb] [-r[revisions]] [-d dates] [-s states]

[-w[logins]] [files...]

- l Local directory only, no recursion.
- R Only print name of RCS file.
- h Only print header.
- t Only print header and descriptive text.
- N Do not list tags.
- b Only list revisions on the default branch.

-r[revisions] Specify revision(s) to list.
    rev1:rev2 Between rev1 and rev2, including rev1 and rev2.
    rev1::rev2 Between rev1 and rev2, excluding rev1 and rev2.
    rev: rev and following revisions on the same branch.
    rev:: After rev on the same branch.
    :rev rev and previous revisions on the same branch.
Before rev on the same branch.

Just rev.

All revisions on the branch.

The last revision on the branch.

Specify dates (D1<D2 for range, D for latest before).

Only list revisions with specified states.

Only list revisions checked in by specified logins.

( Specify the --help global option for a list of other help options )

Options for individual CVS commands (command options) go to the right of the individual command names. Options to the CVS utility itself, such as the help option to the log command, go to the left of all individual command names (that is, they follow the word cvs on the command line). The two types of options sometimes use the same letter yet may have an entirely different meaning.

How CVS Stores Revision Files

With CVS, revision files are kept in a common area called a source repository. This area is identified by the value of the environment variable CVSROOT, which holds the absolute pathname of the repository. The system administrator can tell you what value of CVSROOT to use, or you can create your own private repository and have CVSROOT point to it.

The source repository is organized as a hierarchical collection of files and directories. CVS does not limit you to checking out one file at a time; you can check out an entire subdirectory containing many files: typically all the files for a particular project. A subdirectory of CVSROOT that can be checked out as a single unit is called a module.

Several people can check out and simultaneously modify the files within a single module.

CVS users typically store all the modules they are currently working on in a special directory. If you want to follow this practice, you must use cd to make that special directory the working directory before you check out a module. When you check out a module, CVS replicates the module’s tree structure in the working directory. Multiple developers can check out and edit CVS files simultaneously because the originals are retained in the source repository; the files in the repository undergo relatively infrequent modification in a controlled manner.

Basic Cvs Commands

Although many CVS commands are available, a handful of commands allows a software developer to use CVS and to contribute changes to a module. A discussion of some useful commands follows. All examples assume that the appropriate modules have been installed in the CVS source repository. "Adding a Module to the Repository" (page 426) explains how to install a module.

Of the commands discussed in this section, cvs commit is the only one that changes the source repository. The other commands affect only the files in the working directory.

To simplify examples in the following sections, the pathname of the working directory is given by the variable
To simplify examples in the following sections, the pathname of the working directory is given by the variable `CVSWORK`; all modules can be assumed to be subdirectories of `CVSWORK`. Although this variable has no special meaning to CVS, you may find it helpful to define such a variable for your own work.

Checking Out Files from the Source Repository

To check out a module from the CVS source repository, use the `cvs checkout` command. The following example checks out the `Project2` module, which consists of four source files. First use `cd` to change working directories to the directory you want the module copied into (`CVSWORK` in this case). The `cvs` utility always copies into the working directory.

```
$ cd $CVSWORK
$ ls
Project1
$ cvs checkout Project2
  cvs checkout: Updating Project2
  U Project2/adata.h
  U Project2/compute.c
  U Project2/randomfile.h
  U Project2/shuffle.c
$ ls
Project1 Project2
$ ls Project2
  CVS adata.h compute.c randomfile.h shuffle.c
```

The name of the module, `Project2`, is given as an argument to `cvs checkout`. Because the `Project2` directory does not already exist, `cvs` creates it in the working directory and places copies of all source files for the `Project2` module into it. The name of the module and the name of the directory holding the module are the same. The `checkout` command preserves the tree structure of the `cvs` module, creating subdirectories as needed.

The second `ls` command after `checkout` reveals, in addition to the four source files for `Project2`, a directory named `CVS`. The CVS system uses this directory for administrative purposes; you do not normally access it.

Once you have your own copies of the source files, you can edit them as you see fit. You can change files within the module even if other developers are modifying the same files at the same time.

Making Your Changes Available to Others
To check in your changes so that others have access to them, you need to run the `cvs commit` command. When you give this command, `cvs` prompts you to provide a brief log message describing the changes, unless you use the `-m` option. With this option, `cvs` uses the string following the option as the log message. The file or files that you want to commit follow the optional log message on the command line:

```
$ cvs commit -m "function shuffle inserted" compute.c
```

cvs commit: Up-to-date check failed for 'compute.c'

cvs [commit aborted]: correct above errors first!

Here the `cvs` utility reports an error because the version of `compute.c` that you modified is not up-to-date. A newer version of `compute.c` has been committed by someone else since you last checked it out of the source repository. After informing you of the problem, `cvs` exits without storing your changes in the source repository.

To make your version of `compute.c` current, you need to run the `update` command. A subsequent `commit` will then succeed, and your changes will apply to the latest revision in the source repository.

**Updating Your Copies with Changes by Others**

As the preceding example shows, CVS does not notify you when another developer checks in a new revision of a file after you have checked out your working copy. You learn this fact only when you attempt to commit your changes to the source repository. To incorporate up-to-date revisions of a CVS source file, use the `cvs update` command:

```
$ cvs update compute.c
```

```
RCS file: /usr/local/src/master/Project2/compute.c,v
retrieving revision 1.9
retrieving revision 1.10
Merging differences between 1.9 and 1.10 into compute.c
M compute.c
```

The changes made to the working copy of `compute.c` remain intact because the `update` command merges the latest revision in the source repository with the version specified on the `update` command line. The result of the merge is not always perfect, however. The `cvs update` command informs you if it detects overlapping changes.

**Adding New Files to the Repository**

You can use the `cvs add` command to schedule new files to be added to the source repository as part of the module you are working on. Once you have moved to the directory containing the files, give the `cvs add` command, listing the files you want to add as arguments:
$ cd $CVSWORK/Project2

$ ls
CVS compute.c shuffle.c tabout2.c
adata.h randomfile.h tabout1.c

$ cvs add tabout[1-2].c

cvs add: scheduling file 'tabout1.c' for addition
cvs add: scheduling file 'tabout2.c' for addition
cvs add: use 'cvs commit' to add these files permanently

The **add** command marks the files **tabout1.c** and **tabout2.c** for entry into the repository. These files will not be available for others until you give a **commit** command. This staging allows you to prepare several files before others incorporate the changes into their working copies with the **cvs update** command.

Removing Files from the Repository

The **cvs remove** command records the fact that you wish to remove a file from the source repository. Like the **add** command, it does not affect the source repository. To delete a file from the repository, you must first delete your working copy of the file, as the following example shows:

$ cvs remove shuffle.c

cvs remove: file 'shuffle.c' still in working directory
cvs remove: 1 file exists; use 'rm' to remove it first

$ rm shuffle.c

$ cvs remove shuffle.c

cvs remove: scheduling 'shuffle.c' for removal
cvs remove: use 'cvs commit' to remove this file permanently

After using **rm** to delete the working copy of **shuffle.c**, invoke a **cvs remove** command. Again, you must give the **commit** command before the file is actually removed from the source repository.

Other CVS Commands

Although the commands given earlier are sufficient for most work on a module, you may find some other commands to be useful as well.
Tagging a Release

You can apply a common label, or tag, to the files in a module as they currently exist. Once you have tagged files of a module, you can re-create them in exactly the same form even if they have been modified, added, or deleted since that time. This ability enables you to freeze a release yet allows development to continue on the next release:

$ cvs rtag Release_1 Project1

cvs rtag: Tagging Project1

Here the Project1 module has been tagged with the label Release_1. You can use this tag with the cvs export command to extract the files as they were frozen at this time.

Extracting a Release

The cvs export command lets you extract files as they were frozen and tagged:

$ cvs export -r Release_1 -d R1 Project1

cvs export: Updating R1
U R1/scm.txt

This command works like the cvs checkout command but does not create the CVS support files. You must give either the r option to identify the release (as shown above) or a date with the D option. The d R1 option instructs CVS to place the files for the module into the directory R1 instead of using the module name as the directory.

Removing Working Files

When you are finished making changes to the files you have checked out of the repository, you may decide to remove your copy of the module from your working directory. One simple method is to move into the working directory and recursively remove the module. For example, if you want to remove your working copy of Project2, you could use the following commands:

$ cd $CVSWORK

$ rm -rf Project2

The repository will not be affected by removing these files. However, if you had made changes to the files but had not yet committed those changes, they would be lost if you used this approach. The cvs release command is helpful in this situation:
The release command also removes the working files but first checks each one to see whether it has been marked for addition into the repository but has not yet been committed. If that is the case, the release command warns you and asks you to verify your intention to delete the file. You can fix the problem at this point if you like and redo the release command. The release command also warns you if the repository holds a newer version of the file than the one in your working directory. Thus you have the opportunity to update and commit your file before deleting it. (Without the `-d` option, your working files will not be deleted, but the same sequence of warning messages will be given.)

Adding a Module to the Repository

The discussion of CVS to this point assumes that a module is already present in the CVS source repository. If you want to install a directory hierarchy as a new module in the repository or update an existing module with a new release that was developed elsewhere, go to the directory that holds the files for the project and run the `cvs import` command. The following example installs the files for `Project1` in the source repository:

```
$ cvs import -m "My first project" Project1 ventag reltag
```

The `-m` option allows you to enter a brief description of the module on the command line. Following the description is the directory or the pathname of the directory under CVSROOT that you want to hold the module. The last two fields are symbolic names for the vendor branch and the release. Although they are not significant here, they can be useful when releases of software are supplied by outside sources.

You can now use the `cvs checkout` command to check out the `Project1` module:

```
$ cvs checkout Project1
```

CVS Administration

Before you install a CVS repository, think about how you would like to administer it. Many installations have a single repository where separate projects are kept as separate modules. You may choose to have more than one repository. The CVS system supports a single repository that is shared across several computer systems using NFS.

Inside a repository is a module, named CVSROOT that contains administrative files (here CVSROOT is the name of a module and is different from the CVSROOT directory). Although the files in this module are not required to use CVS, they can simplify access to the repository.

Do not change any files in the CVSROOT module by editing them directly. Instead, check out the file you want to change, edit the checked-out copy, and then check it back in, just as you would with files in any other module in the repository. For example, to check out the modules file from the CVSROOT module, use the command:

```
$ cd $CVSWORK
$ cvs release -d Project2
```
$ cvs checkout CVSROOT/modules

This command creates the directory CVSROOT in your working directory and places a checked-out copy of modules in that directory. After checking it out, you can edit the modules file in the CVSROOT directory:

$ cd CVSROOT

$ vim modules

After you edit the modules file, check it back into the repository:

$ cd ..

$ cvs checkin CVSROOT/modules

Of all the administrative files in the CVSROOT module, the modules file is the most important. You can use this file to attach symbolic names to modules in the repository, allow access to subdirectories of a module as if they were themselves modules, and specify actions to take when checking specific files in or out.

Most repositories start with a modules file that allows you to check out the modules file with the following command, instead of the one shown earlier:

$ cvs checkout modules

With the preceding command CVS creates a subdirectory named modules within the working directory, instead of one named CVSROOT. The modules file is then checked out into this directory.

The following is an example of a modules file (the lines that start with # are comment lines and, along with blank lines, are ignored by CVS):

# The CVS modules file
#
# Three different line formats are valid:
#   key -a aliases...
#   key [options] directory
#   key [options] directory files...
#
# Where "options" are composed of:
# -i prog Run "prog" on "cvs commit" from top-level of module.
# -o prog Run "prog" on "cvs checkout" of module.
# -t prog Run "prog" on "cvs rtag" of module.
# -u prog Run "prog" on "cvs update" of module.
# -d dir Place module in directory "dir" instead of module name.
# -l Top-level directory only -- do not recurse.
#
# And "directory" is a path to a directory relative to $CVSROOT.
#
# The "-a" option specifies an alias. An alias is interpreted as if
# everything on the right of the "-a" had been typed on the command line.
#
# You can encode a module within a module by using the special '&'
# character to interpose another module into the current module. This
# can be useful for creating a module that consists of many directories
# spread out over the entire source repository.
#
# Convenient aliases

world       -a .

# CVSROOT support; run mkmodules whenever anything changes.
CVSROOT     -i mkmodules CVSROOT
modules      -i mkmodules CVSROOT modules
loginfo      -i mkmodules CVSROOT loginfo
commitinfo   -i mkmodules CVSROOT commitinfo
rcsinfo  -i mkmodules CVSROOT rcsinfo
editinfo  -i mkmodules CVSROOT editinfo

# Add other modules here...
testgen  testgen
testdata1 testdata1
testdata2 testdata2
testdata3 testdata3
testdata4 testdata4
testcode  testgen/_code
cvs  cvs

The lines after the comment and blank lines define symbolic names for many modules. For example, the following line defines **world** to be an alias for the root of the CVS repository:

```
world      -a .
```

You can use such names in CVS commands as the names of modules. For example, the following command checks out the entire repository (probably not a good idea):

```
$ cvs checkout world
```

In the sample **modules** file, the administrative files have been given definitions that attach both a symbolic name to the file and an action (*i mkmodules*) to take when each file is checked into the repository. The *i mkmodules* action causes CVS to run the **mkmodules** program when the file is checked in. This program ensures that a copy of the checked-in file exists in a location where CVS can locate it.

Following the action is the name of the subdirectory in **CVSROOT** where any files associated with the symbolic name are located. Any remaining arguments on the line are the names of specific files within that directory.

The following line identifies **CVSROOT** as the name for the module in the directory `$CVSROOT/CVSROOT` that is, for all the administrative files for CVS:

```
CVSROOT      -i mkmodules CVSROOT
```

Similarly the following line associates the **modules** module with the **modules** file within the **CVSROOT** directory:

```
modules      -i mkmodules CVSROOT modules
```
The preceding line allows the following command to find and check out the `modules` file:

```
$ cvs checkout modules
```

The last set of lines in the sample `modules` file associates symbolic module names with directories and files in the repository.

**Using TkCVS**

The `cvs` utility is useful enough that an X Window System interface, TkCVS (www.twobarleycorns.net/tkcvs.html), has been written for it using the Tk extension to the Tcl programming language (tcl.sourceforge.net). It provides a convenient point-and-click interface to CVS (Figure 10-5). After you have downloaded and installed TkCVS, start it by using `cd` to change to the directory you want to work in and entering the following command:

```
$ tkcvs &
```

*Figure 10-5. The TkCVS utility*
All operations are available through the pull-down menus at the top of the window. Along the bottom are buttons for accessing the most common actions. A description of the action bound to a button appears when you position the mouse pointer on top of a button.

In the middle of the window is a browse list. Move into a subdirectory by double-clicking the left mouse button while the mouse pointer is on the directory name in the list. Edit a file by double-clicking the filename. To select more than one file, hold down the left mouse button and drag the mouse pointer across several names. Clicking the right mouse button will mark all selected files. Some of the operations (such as viewing the revision log messages) will work on all marked files.

The Help pull-down menu in the upper-right corner is an excellent way to learn how TkCVS works. For example, when you select the Help menu item CVS modules file..., an explanation of the lines that you can add to the CVS modules file to support TkCVS better appears in a window. If you choose not to add these lines to the modules file, some TkCVS commands, such as browsing the repository, may not display all available modules.
Chapter Summary

The operating system interface to C programs and a variety of software development tools make the Linux system well suited to programming in C. The C libraries provide general-purpose C functions that make operating system services and other functionality available to C programmers. The standard C library libc is always accessible to C programs, and you can specify other libraries by using the -l option to the gcc compiler.

You can write a C program using a text editor, such as vim or emacs. C programs always have a function named main and often include several other functions. Preprocessor directives define symbolic constants and macros and instruct the preprocessor to include header files.

gcc

When you use gcc, it calls the C preprocessor followed by the C compiler and the assembler. The compiler creates assembly language code, which the assembler uses to create object modules. The linker combines these object modules into an executable file. You can use the -Wall option to gcc to detect risky constructions that are legal but suggest the possibility of later problems. Other options to gcc can help locate areas of your code that might not be portable.

gdb

Although using printf statements and the -Wall option can help in tracking program bugs, it is a good practice to compile C programs routinely with the -g option. This option causes information that can be interpreted by gdb, a symbolic debugger, to be generated as part of the executable file. When you run a program under the control of gdb, you can specify points where you want gdb to pause the program, inquire about the values of variables, display the program stack, and use a wide range of commands to learn about many other aspects of the program's behavior.

make

The make utility uses a file named Makefile (or makefile) that documents the relationships among files. It determines which modules of a program are out-of-date and compiles files to keep all modules up-to-date. The dependency line, which specifies the exact dependency relationship between target and prerequisite files, is the key to the operation of a makefile. Following the dependency line are construction commands that can bring the target up-to-date. Implied dependencies, construction commands, and the make macro facility are available to simplify the writing of complex makefiles.

The Linux system includes utilities that assist in keeping track of groups of files that undergo multiple revisions, often at the hands of multiple developers. These source code management systems include CVS, the Concurrent Versions System. CVS is built on top of RCS but provides a much more extensive set of operations for managing directories of files that may be accessed and modified by many users. It is a good choice for large-scale projects and for maintaining software releases that are sent to and from other sites.
Exercises

1. What function does every C program have? Why should you split large programs into several functions?

2. What command could you use to compile `prog.c` and `func.c` into an executable named `cprog`?

3. Show two ways to instruct the C preprocessor to include the header file `/usr/include/math.h` in your C program. Assuming that the `declar.h` header file is located in the subdirectory named `headers` of your home directory, describe two ways to instruct the C preprocessor to include this header file in your C program.

4. How are the names of system libraries abbreviated on the `gcc` command line? Where does `gcc` search for libraries named in this manner? Describe how to specify your own library on the `gcc` command line.

5. Write a makefile that reflects the following relationships:
   
a. The C source files `transactions.c` and `reports.c` are compiled to produce an executable `accts`.

   b. Both `transactions.c` and `reports.c` include a header file `accts.h`.

   c. The header file `accts.h` is composed of two other header files: `trans.h` and `reps.h`.

6. If you retrieve version 4.1 of the file `answer` for editing and then attempt to retrieve the same version again, what will CVS do? Why is CVS set up this way?
Advanced Exercises

7. Modify the `badtabs.c` program (page 409) so that it exits cleanly (with a specific return value). Compile the program and run it using `gdb` or another debugger. What values does the debugger report when the program finishes executing?

8. For the makefile

```
$ cat Makefile
leads: menu.o users.o resellers.o prospects.o
    gcc -o leads menu.o users.o resellers.o prospects.o

menu.o: menu.h dialog.h inquiry.h

users.o: menu.h dialog.h

prospects.o: dialog.h
```

identify:

a. Targets.

b. Construction commands.

c. Prerequisites.

9. Refer to `Makefile` in exercise 8 to answer the following questions:

a. If the target `leads` is up-to-date and you then change `users.c`, what happens when you run `make` again? Be specific.

b. Rewrite the makefile to include the following macros:

```
OBJECTS = menu.o users.o resellers.o prospects.o
HFILES = menu.h dialog.h
```
10. Review the make info page to answer the following questions:

   a. What does the `t` option do?

   b. If you have files named makefile and Makefile in the working directory, how can you instruct make to use Makefile?

   c. Give two ways to define a variable so that you can use it inside a makefile.

11. Refer to the makefile for compute on page 402.

   a. Suppose that a file in the working directory is named `clean`. What is the effect of giving the following command? Explain.

      $ make clean

   b. The discussion on page 401 states that the following command is not normally seen in makefiles:

      `cat num.h table.h > form.h`

      Discuss the effect of removing this construction command from the makefile while retaining the dependency line.

   c. The preceding construction command works only because the file `form.h` is made up of `num.h` and `table.h`. More often `#include` directives in the target define the dependencies. Suggest a more general technique that updates `form.h` whenever `num.h` or `table.h` has a more recent modification date.
Chapter 11. Programming The Bourne Again Shell

IN THIS CHAPTER

Control Structures 436
File Descriptors 470
Parameters and Variables 474
Array Variables 474
Locality of Variables 475
Special Parameters 478
Positional Parameters 480
Builtin Commands 487
Expressions 501
Shell Programs 510
A Recursive Shell Script 510
The quiz Shell Script 513

Chapter 5 introduced the shells and Chapter 8 went into detail about the Bourne Again Shell. This chapter introduces additional Bourne Again Shell commands, builtins, and concepts that carry shell programming to a point where it can be useful. The first part of this chapter covers programming control structures, which are also known as control flow constructs. These structures allow you to write scripts that can loop over command line arguments, make decisions based on the value of a variable, set up menus, and more. The Bourne Again Shell uses the same constructs found in such high-level programming languages as C.

The next part of this chapter discusses parameters and variables, going into detail about array variables, local versus global variables, special parameters, and positional parameters. The exploration of builtin commands covers type, which displays information about a command, and read, which allows you to accept user input in a shell script. The section on the exec builtin demonstrates how exec provides an efficient way to execute a command by replacing a process and explains how you can use it to redirect input and output from within a script. The next section covers the Trap builtin, which provides a way to detect and respond to operating system signals (such as that which is generated when you press CONTROL-C). The discussion of builtins concludes with a discussion of kill, which can abort a process, and getopt, which makes it easy to parse options for a shell script. (Table 11-6 on page 500 lists some of the more commonly used builtins.)

Table 11-6. bash builtins

<table>
<thead>
<tr>
<th>Builtin</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>:</td>
<td>Returns 0 or true (the null builtin; page 495)</td>

<td><strong>unset</strong></td>
<td>Removes a variable or function (page 281)</td>
</tr>
<tr>
<td><strong>wait</strong></td>
<td>Waits for a background process to terminate (page 381)</td>
</tr>
</tbody>
</table>

Next the chapter examines arithmetic and logical expressions and the operators that work with them. The final section walks through the design and implementation of two major shell scripts.

This chapter contains many examples of shell programs. Although they illustrate certain concepts, most use information from earlier examples as well. This overlap not only reinforces your overall knowledge of shell programming but also demonstrates how you can combine commands to solve complex tasks. Running, modifying, and experimenting with the examples in this book is a good way to become comfortable with the underlying concepts.

**tip: Do not name a shell script test**

You can unwittingly create a problem if you give a shell script the name `test` because a Linux utility has the same name. Depending on how the `PATH` variable is set up and how you call the program, you may run your script or the utility, leading to confusing results.

This chapter illustrates concepts with simple examples, which are followed by more complex ones in sections marked "Optional". The more complex scripts illustrate traditional shell programming practices and introduce some Linux utilities often used in scripts. You can skip these sections without loss of continuity the first time you read the chapter. Return to them later when you feel comfortable with the basic concepts.
Control Structures

The control flow commands alter the order of execution of commands within a shell script. The TC Shell uses a different syntax for these commands (page 368) than the Bourne Again Shell does. Control structures include the if...then, for...in, while, until, and case statements. In addition, the break and continue statements work in conjunction with the control structures to alter the order of execution of commands within a script.

if...then

The if...then control structure has the following syntax:

```
if
test-command
then
commands
fi
```

The bold words in the syntax description are the items you supply to cause the structure to have the desired effect. The nonbold words are the keywords the shell uses to identify the control structure.

test builtin

Figure 11-1 shows that the if statement tests the status returned by the test-command and transfers control based on this status. The end of the if structure is marked by a fi statement, (if spelled backward). The following script prompts for two words, reads them, and then uses an if structure to execute commands based on the result returned by the test builtin (tcsh uses the test utility) when it compares the two words. (See page 794 for information on the test utility, which is similar to the test builtin.) The test builtin returns a status of true if the two words are the same and false if they are not. Double quotation marks around $word1 and $word2 make sure that test works properly if you enter a string that contains a SPACE or other special character:

```
$ cat if1

echo -n "word 1: "
read word1

echo -n "word 2: 
read word2

if test "$word1" = "$word2"
    then
```
In the preceding example the test-command is `test "$word1" = "$word2"`. The `test` builtin returns a `true` status if its first and third arguments have the relationship specified by its second argument. If this command returns a `true` status (= 0), the shell executes the commands between the `then` and `fi` statements. If the command returns a `false` status (not = 0), the shell passes control to the statement following `fi` without executing the statements between `then` and `fi`. The effect of this `if` statement is to display `Match` if the two words are the same. The script always displays `End of program.`
In the Bourne Again Shell, `test` is a built-in part of the shell. It is also a stand-alone utility kept in `/usr/bin/test`. This chapter discusses and demonstrates many Bourne Again Shell builtins. Each `bash` builtin may or may not be a builtin in `tcsh`. You usually use the builtin version if it is available and the utility if it is not. Each version of a command may vary slightly from one shell to the next and from the utility to any of the shell builtins. See page 487 for more information on shell builtins.

Checking arguments

The next program uses an `if` structure at the beginning of a script to check that you have supplied at least one argument on the command line. The `eq test` operator compares two integers, where the `$#` special parameter (page 480) takes on the value of the number of command line arguments. This structure displays a message and exits from the script with an exit status of 1 if you do not supply at least one argument:

```bash
$ cat chkargs

if test $# -eq 0
    then
        echo "You must supply at least one argument."
        exit 1
    fi

echo "Program running."

$ chkargs
You must supply at least one argument.

$ chkargs abc
Program running.
```

A test like the one shown in `chkargs` is a key component of any script that requires arguments. To prevent the user from receiving meaningless or confusing information from the script, the script needs to check whether the user has supplied the appropriate arguments. Sometimes the script simply tests whether arguments exist (as in `chkargs`). Other scripts test for a specific number or specific kinds of arguments.

You can use `test` to ask a question about the status of a file argument or the relationship between two file arguments. After verifying that at least one argument has been given on the command line, the following script tests whether the argument is the name of a regular file (not a directory or other type of file) in the working directory. The `test` builtin with the `-f` option and the first command line argument (`$1`) check the file:

```bash
$ cat is_regfile
```
if test $# -eq 0
    then
        echo "You must supply at least one argument."
        exit 1
fi
if test -f "$1"
    then
        echo "$1 is a regular file in the working directory"
    else
        echo "$1 is NOT a regular file in the working directory"
fi

You can test many other characteristics of a file with test and various options. Table 11-1 lists some of these options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Tests file to see if</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Exists and is a directory file</td>
</tr>
<tr>
<td>e</td>
<td>Exists</td>
</tr>
<tr>
<td>f</td>
<td>Exists and is a regular file (not a directory)</td>
</tr>
<tr>
<td>r</td>
<td>Exists and is readable</td>
</tr>
<tr>
<td>s</td>
<td>Exists and has a size greater than 0 bytes</td>
</tr>
<tr>
<td>w</td>
<td>Exists and is writable</td>
</tr>
<tr>
<td>x</td>
<td>Exists and is executable</td>
</tr>
</tbody>
</table>

Other test options provide ways to test relationships between two files, such as whether one file is newer than another. Refer to later examples in this chapter and to test on page 794 for more detailed information.

**tip: Always test the arguments**

To keep the examples in this book short and focused on specific concepts, the code to verify arguments is often omitted or abbreviated. It is a good practice to test arguments in shell programs that other people will use. Doing so results in scripts that are easier to run and debug.

[] is a synonym for test
The following example—another version of `chkargs`—checks for arguments in a way that is more traditional for Linux shell scripts. The example uses the bracket ([ ]) synonym for `test`. Rather than using the word `test` in scripts, you can surround the arguments to `test` with brackets. The brackets must be surrounded by whitespace (SPACES or TABs).

```
$ cat chkargs2

if [ $# -eq 0 ]
then
    echo "Usage: chkargs2 argument..." 1>&2
    exit 1
fi

echo "Program running."

exit 0

$ chkargs2
Usage: chkargs2 arguments

$ chkargs2 abc
Program running.

Usage message

The error message that `chkargs2` displays is called a usage message and uses the 1>&2 notation to redirect its output to standard error (page 260). After issuing the usage message, `chkargs2` exits with an exit status of 1, indicating that an error has occurred. The `exit 0` command at the end of the script causes `chkargs2` to exit with a 0 status after the program runs without an error. The Bourne Again Shell returns a 0 status if you omit the status code.

The usage message is commonly employed to specify the type and number of arguments the script takes. Many Linux utilities provide usage messages similar to the one in `chkargs2`. If you call a utility or other program with the wrong number or kind of arguments, you will often see a usage message. Following is the usage message that `cp` displays when you call it without any arguments:

```
$ cp

cp: missing file argument

Try 'cp --help' for more information.
```
if...then...else

The introduction of an else statement turns the if structure into the two-way branch shown in Figure 11-2. The if...then...else control structure (available in tcsh with a slightly different syntax) has the following syntax:

```
if
test-command
then
commands
else
commands
fi
```

![Figure 11-2. An if ... then ... else flowchart](image)

Because a semicolon (;) ends a command just as a NEWLINE does, you can place then on the same line as if by preceding it with a semicolon. (Because if and then are separate builtins, they require a command separator between them; a semicolon and NEWLINE work equally well.) Some people prefer this notation for aesthetic reasons, while others like it because it saves space:

```
if
test-command;
then
commands
```
If the `test-command` returns a `true` status, the `if` structure executes the commands between the `then` and `else` statements and then diverts control to the statement following `fi`. If the `test-command` returns a `false` status, the `if` structure executes the commands following the `else` statement.

When you run the next script, named `out`, with arguments that are filenames, it displays the files on the terminal. If the first argument is `-v` (called an option in this case), `out` uses `less` (page 45) to display the files one page at a time. After determining that it was called with at least one argument, `out` tests its first argument to see whether it is `-v`. If the result of the test is `true` (if the first argument is `-v`), `out` uses the `shift` builtin to shift the arguments to get rid of the `-v` and displays the files using `less`. If the result of the test is `false` (if the first argument is not `-v`), the script uses `cat` to display the files:

```
$ cat out

if [ $# -eq 0 ]
    then
        echo "Usage: out [-v] filenames..." 1>&2
        exit 1
    fi

if [ "$1" = "-v" ]
    then
        shift
        less -- "$@
    else
        cat -- "$@
    fi
```
optional

In `out` argument to `cat` and `less` tells these utilities that no more options follow on the command line and not to consider leading hyphens (--) in the following list as indicating options. Thus `out` allows you to view a file with a name that starts with a hyphen. Although not common, filenames beginning with a hyphen do occasionally occur. (You can create such a file by using the command `cat > --fname`.) The `out` argument works with all Linux utilities that use the `getopts` builtin (page 497) to parse their options; it does not work with `more` and a few other utilities. This argument is particularly useful when used in conjunction with `rm` to remove a file whose name starts with a hyphen (`rm --fname`), including any that you create while experimenting with the `out` argument.

if...then...elif

The `if...then...elif` control structure (Figure 11-3; not available in `tcsh`) has the following syntax:

```
if
test-command
then
commands
elif
test-command
then
commands
...
else
commands
fi
```

Figure 11-3. An if ... then ... elif flowchart
The `elif` statement combines the `else` statement and the `if` statement and allows you to construct a nested set of `if...then...else` structures (Figure 11-3). The difference between the `else` statement and the `elif` statement is that each `else` statement must be paired with a `fi` statement, whereas multiple nested `elif` statements require only a single closing `fi` statement.

The following example shows an `if...then...elif` control structure. This shell script compares three words that the user enters. The first `if` statement uses the Boolean operator AND (\&\&) as an argument to `test`. The `test` builtin returns a `true` status only if the first and second logical comparisons are `true` (that is, if `word1` matches `word2` and `word2` matches `word3`). If `test` returns a `true` status, the script executes the command following the next `then` statement, passes control to the statement following `fi`, and terminates:
$ cat if3

echo -n "word 1: "
read word1

echo -n "word 2: "
read word2

echo -n "word 3: "
read word3

if [ "$word1" = "$word2" -a "$word2" = "$word3" ]
  then
    echo "Match: words 1, 2, & 3"
  elif [ "$word1" = "$word2" ]
    then
        echo "Match: words 1 & 2"
      elif [ "$word1" = "$word3" ]
        then
            echo "Match: words 1 & 3"
      elif [ "$word2" = "$word3" ]
        then
            echo "Match: words 2 & 3"
      else
        echo "No match"
  fi

$ if3

word 1: apple
word 2: orange
word 3: pear
No match

$ if3

word 1: apple

word 2: orange

word 3: apple

Match: words 1 & 3

$ if3

word 1: apple

word 2: apple

word 3: apple

Match: words 1, 2, & 3

If the three words are not the same, the structure passes control to the first \texttt{elif}, which begins a series of tests to see if any pair of words is the same. As the nesting continues, if any one of the \texttt{if} statements is satisfied, the structure passes control to the next \texttt{then} statement and subsequently to the statement following \texttt{fi}. Each time an \texttt{elif} statement is not satisfied, the structure passes control to the next \texttt{elif} statement. The double quotation marks around the arguments to \texttt{echo} that contain ampersands (&) prevent the shell from interpreting the ampersands as special characters.
optional: The **lnks** Script

The following script, named **lnks**, demonstrates the **if...then** and **if...then...elif** control structures. This script finds hard links to its first argument, a filename. If you provide the name of a directory as the second argument, **lnks** searches for links in that directory and all subdirectories. If you do not specify a directory, **lnks** searches the working directory and its subdirectories. This script does not locate symbolic links.

$ cat lnks

#!/bin/bash

# Identify links to a file
# Usage: lnks file [directory]

if [ $# -eq 0 -o $# -gt 2 ]; then
    echo "Usage: lnks file [directory]" 1>&2
    exit 1
fi

if [ -d "$1" ]; then
    echo "First argument cannot be a directory." 1>&2
    echo "Usage: lnks file [directory]" 1>&2
    exit 1
else
    file="$1"
fi

if [ $# -eq 1 ]; then
    directory="."
    elif [ -d "$2" ]; then
        directory="$2"
    else
        echo "Optional second argument must be a directory." 1>&2
    fi
echo "Usage: lnks file [directory]" 1>&2
exit 1
fi

# Check that file exists and is a regular file:
if [ ! -f "$file" ]; then
    echo "lnks: $file not found or special file" 1>&2
    exit 1
fi

# Check link count on file
set -- $(ls -l "$file")

linkcnt=$2
if [ "$linkcnt" -eq 1 ]; then
    echo "lnks: no other hard links to $file" 1>&2
    exit 0
fi

# Get the inode of the given file
set $(ls -i "$file")
inode=$1

# Find and print the files with that inode number
echo "lnks: using find to search for links..." 1>&2
find "$directory" -xdev -inum $inode -print
Alex has a file named letter in his home directory. He wants to find links to this file in his and other users' home directory file trees. In the following example, Alex calls lnks from his home directory to perform the search. The second argument to lnks, /home, is the pathname of the directory he wants to start the search in. The lnks script reports that /home/alex/letter and /home/jenny/draft are links to the same file:

```bash
$ lnks letter /home
lnks: using find to search for links...
/home/alex/letter
/home/jenny/draft
```

In addition to the if...then...elif control structure, lnks introduces other features that are commonly used in shell programs. The following discussion describes lnks section by section.

Specify the shell

The first line of the lnks script uses #! (page 265) to specify the shell that will execute the script:

```bash
#!/bin/bash
```

In this chapter the #! notation appears only in more complex examples. It ensures that the proper shell executes the script, even when the user is running a different shell or the script is called from another shell script.

Comments

The second and third lines of lnks are comments; the shell ignores the text that follows a pound sign up to the next NEWLINE character. These comments in lnks briefly identify what the file does and how to use it:

```
# Identify links to a file
# Usage: lnks file [directory]
```

Usage messages

The first if statement tests whether lnks was called with zero arguments or more than two arguments:
if [ $# -eq 0 -o $# -gt 2 ]; then
    echo "Usage: lnks file [directory]" 1>&2
    exit 1
fi

If either of these conditions is true, lnks sends a usage message to standard error and exits with a status of 1. The double quotation marks around the usage message prevent the shell from interpreting the brackets as special characters. The brackets in the usage message indicate that the directory argument is optional.

The second if statement tests whether the first command line argument ($1) is a directory (the -d argument to test returns a true value if the file exists and is a directory):

if [ -d "$1" ]; then
    echo "First argument cannot be a directory." 1>&2
    echo "Usage: lnks file [directory]" 1>&2
    exit 1
else
    file="$1"
fi

If the first argument is a directory, lnks displays a usage message and exits. If it is not a directory, lnks saves the value of $1 in the file variable because later in the script set resets the command line arguments. If the value of $1 is not saved before the set command is issued, its value will be lost.

Test the arguments

The next section of lnks is an if...then...elif statement:

if [ $# -eq 1 ]; then
    directory="."
    elif [ -d "$2" ]; then
        directory="$2"
else
    echo "Optional second argument must be a directory." 1>&2
    echo "Usage: lnks file [directory]" 1>&2
    exit 1
fi

The first `test-command` determines whether the user specified a single argument on the command line. If the `test-command` returns 0 (true), the user-created variable named `directory` is assigned the value of the working directory (.). If the `test-command` returns false, the `elif` statement tests whether the second argument is a directory. If it is a directory, the `directory` variable is set equal to the second command line argument, `$2`. If `$2` is not a directory, `lnks` sends a usage message to standard error and exits with a status of 1.

The next `if` statement in `lnks` tests whether `$file` does not exist. This test keeps `lnks` from wasting time looking for links to a nonexistent file.

The `test` builtin with the three arguments !, f, and `$file` evaluates to `true` if the file `$file` does not exist:

```
[ ! -f "$file" ]
```

The ! operator preceding the f argument to `test` negates its result, yielding `false` if the file `$file` does exist and is a regular file.

Next `lnks` uses `set` and `ls -l` to check the number of links `$file` has:

```
# Check link count on file
set -- $(ls -l "$file")

linkcnt=$2
if [ "$linkcnt" -eq 1 ]; then
    echo "lnks: no other hard links to $file" 1>&2
    exit 0
fi
```
The `set` builtin uses command substitution (page 329) to set the positional parameters to the output of `ls -l`. The second field in this output is the link count, so the user-created variable `linkcnt` is set equal to `$2`. The `set` used with `set` prevents `set` from interpreting as an option the first argument produced by `ls -l` (the first argument is the access permissions for the file and typically begins with `-`). The `if` statement checks whether `linkcnt` is equal to 1; if it is, `lnks` displays a message and exits. Although this message is not truly an error message, it is redirected to standard error. The way `lnks` has been written, all informational messages are sent to standard error. Only the final product of `lnks`—the pathnames of links to the specified file—is sent to standard output, so you can redirect the output as you please.

If the link count is greater than one, `lnks` goes on to identify the `inode` (page 880) for `$file`. As explained on page 99, comparing the inodes associated with filenames is a good way to determine whether the filenames are links to the same file. The `lnks` script uses `set` to set the positional parameters to the output of `ls -i`. The first argument to `set` is the inode number for the file, so the user-created variable named `inode` is assigned the value of `$1`:

```bash
# Get the inode of the given file
set $(ls -i "$file")
inode=$1
```

Finally `lnks` uses the `find` utility (page 655) to search for files having inode numbers that match `inode`:

```bash
# Find and print the files with that inode number
echo "lnks: using find to search for links..." 1>&2
find "$directory" -xdev -inum $inode -print
```

The `find` utility searches for files that meet the criteria specified by its arguments, beginning its search with the directory specified by its first argument (`$directory`) and searching all subdirectories. The remaining arguments specify that the filenames of files having inodes matching `inode` should be sent to standard output. Because files in different filesystems can have the same inode number and not be linked, `find` must search only directories in the same filesystem as `$directory`. The `xdev` argument prevents `find` from searching directories on other filesystems. Refer to page 96 for more information about filesystems and links.

The `echo` command preceding the `find` command in `lnks`, which tells the user that `find` is running, is included because `find` frequently takes a long time to run. Because `lnks` does not include a final exit statement, the exit status of `lnks` is that of the last command it runs, `find`. 
**DEBUGGING SHELL SCRIPTS**

When you are writing a script such as `lnks`, it is easy to make mistakes. You can use the shell's `x` option to help debug a script. This option causes the shell to display each command before it runs the command. Tracing a script's execution in this way can give you information about where a problem lies.

You can run `lnks` as in the previous example and cause the shell to display each command before it is executed. Either set the `x` option for the current shell (`set x`) so that all scripts display commands as they are run or use the `x` option to affect only the shell that is running the script called by the command line.

```
$ bash -x lnks letter /home
+ '[ ' 2 -eq 0 -o 2 -gt 2 ' ]'
+ '[ ' -d letter ' ]'
+ file=letter
+ '[ ' 2 -eq 1 ' ]'
+ '[ ' -d /home ' ]'
+ directory=/home
+ '[ ' '! ' -f letter ' ]'
...
```

**PS4**

Each command that the script executes is preceded by the value of the `PS4` variable, a plus sign (+) by default, so you can distinguish debugging output from script-produced output. You must export `PS4` if you set it in the shell that calls the script. The next command sets `PS4` to >>>> followed by a SPACE and exports it:

```
$ export PS4='>>>> '
```

You can also set the `x` option of the shell running the script by putting the following `set` command at the top of the script:

```
set -x
```
Put `set -x` anywhere in the script you want to turn debugging on. Turn the debugging option off with a plus sign.

```
set +x
```

The `set -o xtrace` and `set +o xtrace` commands do the same things as `set -x` and `set +x`, respectively.

**for...in**

The **for...in** control structure (**tcsh** uses **foreach**) has the following syntax:

```
for
  loop-index
in
  argument-list
do

  commands

done
```

The **for...in** structure (**Figure 11-4**) assigns the value of the first argument in the **argument-list** to the **loop-index** and executes the **commands** between the **do** and **done** statements. The **do** and **done** statements mark the beginning and end of the **for** loop.

**Figure 11-4. A for ... in flowchart**
After it passes control to the `done` statement, the structure assigns the value of the second argument in the `argument-list` to the `loop-index` and repeats the `commands`. The structure repeats the `commands` between the `do` and `done` statements one time for each argument in the `argument-list`. When the structure exhausts the `argument-list`, it passes control to the statement following `done`.

The following `for...in` structure assigns `apples` to the user-created variable `fruit` and then displays the value of `fruit`, which is `apples`. Next the structure assigns `oranges` to `fruit` and repeats the process. When it exhausts the argument list, the structure transfers control to the statement following `done`, which displays a message.

```
$ cat fruit
for fruit in apples oranges pears bananas
do
    echo "$fruit"
done
echo "Task complete."
```
Task complete.

The next script lists the names of the directory files in the working directory by looping over all the files, using `test` to determine which files are directories:

```
$ cat dirfiles
for i in *
do
  if [ -d "$i" ]
    then
      echo "$i"
    fi
done
```

The ambiguous file reference character `*` matches the names of all files (except invisible files) in the working directory. Prior to executing the `for` loop, the shell expands the `*` and uses the resulting list to assign successive values to the index variable `i`.

The `for` control structure (not available in `tcsh`) has the following syntax:

```
for
  loop-index
do
  commands
done
```
In the **for** structure the **loop-index** takes on the value of each of the command line arguments, one at a time. It is the same as the **for...in** structure (Figure 11-4) except for where it gets values for the **loop-index**. The **for** structure performs a sequence of commands, usually involving each argument in turn.

The following shell script shows a **for** structure displaying each command line argument. The first line of the script, **for arg**, implies **for arg in "$@"**, where the shell expands "$@" into a list of quoted command line arguments "$1" "$2" "$3" and so on. The balance of the script corresponds to the **for...in** structure.

```
$ cat for_test
for arg
do
echo "$arg"
done

$ for_test candy gum chocolate

candy
gum
chocolate
```
optional: The **whos** Script

The following script, named **whos**, demonstrates the usefulness of the implied "$@" in the **for** structure. You give **whos** one or more user or login names as arguments, and **whos** displays information about the users. The **whos** script gets the information it displays from the first and fifth fields in the **/etc/passwd** file. The first field always contains a username, and the fifth field typically contains the user's full name. You can provide a login name as an argument to **whos** to identify the user's name or provide a name as an argument to identify the username. The **whos** script is similar to the **finger** utility, although **whos** delivers less information.

```bash
$ cat whos

#!/bin/bash

# adapted from finger.sh by Lee Sailer
# UNIX/WORLD, III:11, p. 67, Fig. 2

if [ $# -eq 0 ]
    then
        echo "Usage: whos id..." 1>&2
        exit 1
fi

for id
do
gawk -F: '{print $1, $5}' /etc/passwd |
grep -i "$id"
done

Below **whos** identifies the user whose username is **chas** and the user whose name is **Marilou Smith**:

$ whos chas "Marilou Smith"
chas Charles Casey
```
msmith Marilou Smith

Use of "@"

The `whos` script uses a `for` statement to loop through the command line arguments. In this script the implied use of "@" in the `for` loop is particularly beneficial because it causes the `for` loop to treat an argument that contains a `SPACE` as a single argument. This example quotes `Marilou Smith`, which causes the shell to pass it to the script as a single argument. Then the implied "@" in the `for` statement causes the shell to regenerate the quoted argument `Marilou Smith` so that it is again treated as a single argument.

`gawk`

For each command line argument, `whos` searches the `/etc/passwd` file. Inside the `for` loop the `gawk` utility (Chapter 12) extracts the first (`$1`) and fifth (`$5`) fields from the lines in `/etc/passwd`. The `-F:` option causes `gawk` to use a colon (:) as a field separator when it reads `/etc/passwd`, allowing it to break each line into fields. The `gawk` command sets and uses the `$1` and `$5` arguments; they are included within single quotation marks and are not interpreted by the shell. Do not confuse these arguments with positional parameters, which correspond to command line arguments. The first and fifth fields are sent to `grep` (page 683) via a pipe. The `grep` utility searches for `$id` (which has taken on the value of a command line argument) in its input. The `-i` option causes `grep` to ignore case as it searches; `grep` displays each line in its input that contains `$id`.

`|` at the end of a line

An interesting syntactical exception that `bash` gives the pipe symbol (`|`) appears on the line with the `gawk` command: You do not have to quote a `NEWLINE` that immediately follows a pipe symbol (that is, a pipe symbol that is the last thing on a line) to keep the `NEWLINE` from executing a command. Try giving the command `who |` and pressing RETURN. The shell (not `tcsh`) displays a secondary prompt. If you then enter `sort` followed by another RETURN, you see a sorted `who` list. The pipe works even though a `NEWLINE` follows the pipe symbol.

`while`

The `while` control structure (not available in `tcsh`) has the following syntax:

```
while
test-command
do

commands
done
```
As long as the **test-command** (Figure 11-5) returns a *true* exit status, the **while** structure continues to execute the series of **commands** delimited by the **do** and **done** statements. Before each loop through the **commands**, the structure executes the **test-command**. When the exit status of the **test-command** is *false*, the structure passes control to the statement after the **done** statement.

Figure 11-5. A while flowchart

The following shell script first initializes the **number** variable to zero. The **test** builtin then determines whether **number** is less than 10. The script uses **test** with the `-lt` argument to perform a numerical test. For numerical comparisons, you must use `-ne` (not equal), `-eq` (equal), `-gt` (greater than), `-ge` (greater than or equal to), `-lt` (less than), or `-le` (less than or equal to). For string comparisons use `=` (equal) or `!=` (not equal) when you are working with **test**. In this example, **test** has an exit status of 0 (*true*) as long as **number** is less than 10. As long as **test** returns *true*, the structure executes the commands between the **do** and **done** statements. See page 794 for information on the **test** utility, which is very similar to the **test** builtin.

$ cat count

```
#!/bin/bash

number=0

while [ "number" -lt 10 ]
  do
    echo -n "$number"

```
((number +=1))

done

echo

$ count

0123456789

$

The `echo` command following `do` displays `number`. The `in` prevents `echo` from issuing a `NEWLINE` following its output. The next command uses arithmetic evaluation `[((...));` page 501] to increment the value of `number` by 1. The `done` statement terminates the loop and returns control to the `while` statement to start the loop over again. The final `echo` causes `count` to send a `NEWLINE` character to standard output, so that the next prompt occurs in the leftmost column on the display (rather than immediately following 9).
optional: The spell_check Script

The `aspell` utility checks the words in a file against a dictionary of correctly spelled words. With the `-l` option, `aspell` runs in list mode: Input comes from standard input and `aspell` sends each potentially misspelled word to standard output. The following command produces a list of possible misspellings in the file `letter.txt`:

```
$ aspell -l < letter.txt
quikly
portible
frendly
```

The next shell script, named `spell_check`, shows another use of a `while` structure. To find the incorrect spellings in a file, you can use `spell_check`, which calls `aspell` to check a file against a system dictionary but goes a step further: It enables you to specify a list of correctly spelled words and removes these words from the output of `aspell`. This script is useful for removing words that you use frequently, such as names and technical terms, that are not in a standard dictionary. Although you can duplicate the functionality of `spell_check` by using additional `aspell` dictionaries, the script is included here for its instructive value.

The `spell_check` script requires two filename arguments: a file containing the list of correctly spelled words and a file that you want to check. The first `if` statement verifies that the user specified two arguments. The next two `if` statements verify that both arguments are readable files. (The exclamation point negates the sense of the following operator; the `r` operator causes `test` to determine whether a file is readable. The result is a test that determines whether a file is *not* readable.)

```
$ cat spell_check

#!/bin/bash

# remove correct spellings from aspell output

if [ $# -ne 2 ]; then
    echo "Usage: spell_check file1 file2" 1>&2
    echo "file1: list of correct spellings" 1>&2
    echo "file2: file to be checked" 1>&2
```
The `spell_check` script sends the output from `aspell` (with the `-l` option so that it produces a list of misspelled words on standard output) through a pipe to standard input of a `while` structure, which reads one line at a time (each line has one word on it) from standard input. The `test-command` (that is, `read line`) returns a `true` exit status as long as it receives a line from standard input.
Inside the \texttt{while} loop an \texttt{if} statement\cite{1} monitors the return value of \texttt{grep}, which determines whether the line that was read is in the user's list of correctly spelled words. The pattern that \texttt{grep} searches for (the value of \texttt{Sline}) is preceded and followed by special characters that specify the beginning and end of a line (\texttt{^} and \texttt{$}, respectively). These special characters ensure that \texttt{grep} finds a match only if the \texttt{Sline} variable matches an entire line in the file of correctly spelled words. (Otherwise, \texttt{grep} would match a string, such as \texttt{paul}, in the output of \texttt{aspell} if the file of correctly spelled words contained the word \texttt{paulson}.) These special characters, together with the value of the \texttt{Sline} variable, form a regular expression (Appendix A).

The output of \texttt{grep} is redirected to \texttt{/dev/null} (page 122) because the output is not needed; only the exit code is important. The \texttt{if} statement checks the negated exit status of \texttt{grep} (the leading exclamation point negates or changes the sense of the exit status/\texttt{true} becomes \texttt{false}, and vice versa), which is 0 or \texttt{true} (\texttt{false} when negated) when a matching line is found. If the exit status is \texttt{not 0} or \texttt{false} (\texttt{true} when negated), the word was \texttt{not} in the file of correctly spelled words. The \texttt{echo} builtin sends a list of words that are not in the file of correctly spelled words to standard output.

Once it detects the EOF (end of file), the \texttt{read} builtin returns a \texttt{false} exit status. Control then passes out of the \texttt{while} structure, and the script terminates.

Before you use \texttt{spell_check}, create a file of correct spellings containing words that you use frequently but that are not in a standard dictionary. For example, if you work for a company named \texttt{Blinkenship and Klimowski, Attorneys}, you would put \texttt{Blinkenship} and \texttt{Klimowski} into the file. The following example shows how \texttt{spell_check} checks the spelling in a file named \texttt{memo} and removes \texttt{Blinkenship} and \texttt{Klimowski} from the output list of incorrectly spelled words:

\begin{verbatim}
$ aspell -l < memo
Blinkenship
Klimowski
targat
hte
$ cat word_list
Blinkenship
Klimowski
$ spell_check word_list memo
targat
hte
\end{verbatim}

Refer to page 589 for more information on \texttt{aspell}.

\cite{1}This \texttt{if} statement can also be written as
if ! grep -qw "$line" "$1"

The `q` option suppresses the output from grep so that only an exit code is returned. The `w` option causes grep to match only a whole word.

**until**

The `until` (not available in `tcsh`) and `while` (available in `tcsh` with a slightly different syntax) structures are very similar, differing only in the sense of the test performed at the top of the loop. Figure 11-6 shows that `until` continues to loop until the `test-command` returns a `true` exit status. The `while` structure loops while the `test-command` continues to return a `true` or nonerror condition. The `until` control structure has the following syntax:

```
until
  test-command
  do
    commands
  done
```

![Figure 11-6. An until flowchart](image)

The following script demonstrates an `until` structure that includes `read`. When the user enters the correct string of characters, the `test-command` is satisfied and the structure passes control out of the loop.
The following `locktty` script is similar to the `lock` command on Berkeley UNIX and the `Lock Screen` menu selection in GNOME. The script prompts you for a key (password) and uses an `until` control structure to lock the terminal. The `until` statement causes the system to ignore any characters typed at the keyboard until the user types in the key on a line by itself, which unlocks the terminal. The `locktty` script can keep people from using your terminal while you are away from it for short periods of time. It saves you from having to log out if you are concerned about other users using your login.
#!/bin/bash

# UNIX/WORLD, III:4

trap '' 1 2 3 18
stty -echo

echo -n "Key: 
read key_1

echo

echo -n "Again: 
read key_2

echo

key_3=

if [ "$key_1" = "$key_2" ]
then
tput clear

until [ "$key_3" = "$key_2" ]
do

read key_3
done
else

echo "locktty: keys do not match" 1>&2
fi

stty echo

**tip: Forget your password for locktty?**

If you forget your key (password), you will need to log in from another (virtual) terminal and kill the process running **locktty**.
The `trap` builtin (page 493; not available in `tcsh`) at the beginning of the `locktty` script stops a user from being able to terminate the script by sending it a signal (for example, by pressing the interrupt key). Trapping signal 18 means that no one can use `CONTROL-Z` (job control, a stop from a tty) to defeat the lock. (See Table 11-5 on page 494 for a list of signals.) The `stty echo` command (page 778) causes the terminal not to display characters typed at the keyboard, thereby preventing the key that the user enters from appearing on the screen. After turning off keyboard echo, the script prompts the user for a key, reads it into the user-created variable `key_1`, prompts the user to enter the same key again, and saves it in `key_2`. The statement `key_3=` creates a variable with a `NULL` value. If `key_1` and `key_2` match, `locktty` clears the screen (with the `tput` command) and starts an `until` loop. The `until` loop keeps attempting to read from the terminal and assigning the input to the `key_3` variable. Once the user types in a string that matches one of the original keys (`key_2`), the `until` loop terminates and keyboard echo is turned on again.

### Table 11-5. Signals

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Number</th>

<td>Executes <code>commands</code> specified in the <code>TRap</code> statement after each command that returns a nonzero exit status (not an actual signal but useful in <code>TRap</code>)</td>
</tr>
</tbody>
</table>

### break AND continue

You can interrupt a `for`, `while`, or `until` loop by using a `break` or `continue` statement. The `break` statement transfers control to the statement after the `done` statement, which terminates execution of the loop. The `continue` command transfers control to the `done` statement, which continues execution of the loop.

The following script demonstrates the use of these two statements. The `for...in` structure loops through the values 1–10. The first `if` statement executes its commands when the value of the index is less than or equal to 3 (`$index le 3`). The second `if` statement executes its commands when the value of the index is greater than or equal to 8 (`$index ge 8`). In between the two `ifs`, `echo` displays the value of the index. For all values up to and including 3, the first `if` statement displays `continue` and executes a `continue` statement that skips `echo $index` and the second `if` statement and continues with the next `for` statement. For the value of 8, the second `if` statement displays `break` and executes a `break` statement that exits from the `for` loop:
```bash
$ cat brk
for index in 1 2 3 4 5 6 7 8 9 10
  do
    if [ $index -le 3 ]; then
        echo "continue"
        continue
    fi
    #
    echo $index
    #
    if [ $index -ge 8 ]; then
        echo "break"
        break
    fi
  done

$ brk
continue
continue
continue
continue
4
5
6
7
8
break
```
The case structure (Figure 11-7, page 461) is a multiple-branch decision mechanism. The path taken through the structure depends on a match or lack of a match between the test-string and one of the patterns. The case control structure (tcsh uses switch) has the following syntax:

```bash
  case
test-string
  in
  pattern-1)
  commands-1
  ;;
  pattern-2)
  commands-2
  ;;
  pattern-3)
  commands-3
  ;;
  ...
esac
```

Figure 11-7. A case flowchart
The following case structure examines the character that the user enters as the test-string. This value is held in the variable letter. If the test-string has a value of A, the structure executes the command following the pattern A. The right parenthesis is part of the case control structure, not part of the pattern. If the test-string has a value of B or C, the structure executes the command following the matching pattern. The asterisk (*) indicates any string of characters and serves as a catchall in case there is no match. If no pattern matches the test-string and if there is no catchall (*) pattern, control passes to the command following the esac statement, without the case structure taking any action.

```bash
$ cat case1

echo -n "Enter A, B, or C: 

read letter
```
case "$letter" in
  A)
    echo "You entered A"
    ;;
  B)
    echo "You entered B"
    ;;
  C)
    echo "You entered C"
    ;;
  *)
    echo "You did not enter A, B, or C"
    ;;
esac

$ case1
Enter A, B, or C: B
You entered B

The next execution of case1 shows the user entering a lowercase b. Because the test-string b does not match the uppercase B pattern (or any other pattern in the case statement), the program executes the commands following the catchall pattern and displays a message:

$ case1
Enter A, B, or C: b
You did not enter A, B, or C

The pattern in the case structure is analogous to an ambiguous file reference. It can include any of the special characters and strings shown in Table 11-2.
Table 11-2. Patterns

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Matches any string of characters. Use for the default case.</td>
</tr>
<tr>
<td>?</td>
<td>Matches any single character.</td>
</tr>
<tr>
<td>[...]</td>
<td>Defines a character class. Any characters enclosed within brackets are tried, one at a time, in an attempt to match a single character. A hyphen between two characters specifies a range of characters.</td>
</tr>
<tr>
<td></td>
<td>Separates alternative choices that satisfy a particular branch of the case structure.</td>
</tr>
</tbody>
</table>

The next script accepts both uppercase and lowercase letters:

```
$ cat case2

echo -n "Enter A, B, or C: "
read letter
case "$letter" in
  a|A)
    echo "You entered A"
    ;
  b|B)
    echo "You entered B"
    ;
  c|C)
    echo "You entered C"
    ;
  *)
    echo "You did not enter A, B, or C"
    ;
esac

$ case2
Enter A, B, or C: b
You entered B
```
The following example shows how you can use the `case` structure to create a simple menu. The `command_menu` script uses `echo` to present menu items and prompt the user for a selection. (The `select` control structure [page 466] makes it much easier to code a menu.) The `case` structure then executes the appropriate utility depending on the user's selection.

```
$ cat command_menu
#!/bin/bash

# menu interface to simple commands

echo -e "\n COMMAND MENU\n"
echo "  a. Current date and time"
echo "  b. Users currently logged in"
echo "  c. Name of the working directory"
# echo -e "  d. Contents of the working directory\n"
echo -n "Enter a, b, c, or d: "
read answer

echo
case "$answer" in
  a)
    date
    ;;
  b)
    who
    ;;
  c)
    pwd
    ;;
```
d)  
   ls  
   ;;  
*)  
   echo "There is no selection: $answer"
   ;;  
esac

$ command_menu

COMMAND MENU

a. Current date and time
b. Users currently logged in
c. Name of the working directory
d. Contents of the working directory

Enter a, b, c, or d: a

Wed Jan 5 12:31:12 PST 2005

echo \n
The `\n` option causes `echo` to interpret `\n` as a NEWLINE character. If you do not include this option, `echo` does not output the extra blank lines that make the menu easy to read but instead outputs the (literal) two-character sequence `\n`. The `\n` option causes `echo` to interpret several other backslash-quoted characters (Table 11-3). Remember to quote (i.e., place double quotation marks around the string) the backslash-quoted character so that the shell does not interpret it but passes the backslash and the character to `echo`. See `xpg_echo` (page 322) for a way to avoid using the `\n` option.
Table 11-3. Special characters in `echo` (must use `\` before `e`)

<table>
<thead>
<tr>
<th>Quoted character</th>

</tr>
</tbody>
</table>

You can also use the `case` control structure to take various actions in a script, depending on how many arguments the script is called with. The following script, named `safedit`, uses a `case` structure that branches based on the number of command line arguments (`$#`). It saves a backup copy of a file you are editing with `vim`.

```
$ cat safedit

#!/bin/bash

# UNIX/WORLD, IV:11

PATH=/bin:/usr/bin

script=$(basename $0)

#case $# in

0)
    vim
    exit 0
    ;;

1)
    if [ ! -f "$1" ]
    then

```
vim "$1"
exit 0
fi
if [ ! -r "$1" -o ! -w "$1" ]
then
echo "$script: check permissions on $1" 1>&2
exit 1
else
editfile=$1
fi
if [ ! -w "." ]
then
echo "$script: backup cannot be " \
"created in the working directory" 1>&2
exit 1
fi
;;
*)
echo "Usage: $script [file-to-edit]" 1>&2
exit 1
;;
esac
tempfile=/tmp/$$.script

cp $editfile $tempfile
if vim $editfile
    then
        mv $tempfile bak.$(basename $editfile)
        echo "$script: backup file created"
    else
        mv $tempfile editerr
        echo "$script: edit error--copy of " \
        "original file is in editerr" 1>&2
fi

If you call `safedit` without any arguments, the `case` structure executes its first branch and calls `vim` without a filename argument. Because an existing file is not being edited, `safedit` does not create a backup file. (See the `:w` command on page 153 for an explanation of how to exit from `vim` when you have called it without a filename.) If you call `safedit` with one argument, it runs the commands in the second branch of the `case` structure and verifies that the file specified by `$1` does not yet exist or is the name of a file for which the user has read and write permission. The `safedit` script also verifies that the user has write permission for the working directory. If the user calls `safedit` with more than one argument, the third branch of the `case` structure presents a usage message and exits with a status of 1.

Set `PATH`

In addition to using a `case` structure for branching based on the number of command line arguments, the `safedit` script introduces several other features. First, at the beginning of the script, the `PATH` variable is set to search `/bin` and `/usr/bin`. Setting `PATH` in this way ensures that the commands executed by the script are standard utilities, which are kept in those directories. By setting `PATH` inside a script, you can avoid the problems that might occur if users have set `PATH` to search their own directories first and have scripts or programs with the same names as the utilities the script calls. You can also include absolute pathnames within a script to achieve this end, but this practice can make a script less portable.

Name of the program

In a second `safedit` feature, the following line creates a variable named `script` and assigns the simple filename of the script to it:

```
script=$(basename $0)
```

The `basename` utility sends the simple filename component of its argument to standard output, which is assigned to the `script` variable, using command substitution. The `$0` holds the command the script was called with (page 481). No matter which of the following commands the user calls the script with,
the output of `basename` is the simple filename `safedit`:

```
$ /home/alex/bin/safedit memo
$ ./safedit memo
$ safedit memo
```

After the `script` variable is set, it replaces the filename of the script in usage and error messages. By using a variable that is derived from the command that invoked the script rather than a filename that is hardcoded into the script, you can create links to the script or rename it, and the usage and error messages will still provide accurate information.

Naming temporary files

A third significant feature of `safedit` relates to the use of the `$$` variable in the name of a temporary file. The statement following the `esac` statement creates and assigns a value to the `tempfile` variable. This variable contains the name of a temporary file that is stored in the `/tmp` directory, as are many temporary files. The temporary filename begins with the PID number of the shell and ends with the name of the script. Use of the PID number ensures that the filename is unique, and `safedit` will not attempt to overwrite an existing file, as might happen if two people were using `safedit` at the same time. The name of the script is appended so that, should the file be left in `/tmp` for some reason, you can figure out where it came from.

The PID number is used in front of rather than after `$script` in the filename because of the 14-character limit placed on filenames by some older versions of UNIX. Linux systems do not have this limitation. Because the PID number ensures the uniqueness of the filename, it is placed first so that it cannot be truncated. (If the `$script` component is truncated, the filename is still unique.) For the same reason, when a backup file is created inside the `if` control structure a few lines down in the script, the filename is composed of the string `bak`, followed by the name of the file being edited. On an older system, if `bak` were used as a suffix rather than a prefix and the original filename were 14 characters long, `.bak` might be lost and the original file would be overwritten. The `basename` utility extracts the simple filename of `$editfile` before it is prefixed with `bak`.

Fourth, `safedit` uses an unusual `test-command` in the `if` structure: `vim $editfile`. The `test-command` calls `vim` to edit `$editfile`. When you finish editing the file and exit from `vim`, `vim` returns an exit code. The `if` control structure uses that exit code to determine which branch to take. If the editing session completed successfully, `vim` returns 0 and the statements following the `then` statement are executed. If `vim` does not terminate normally (as would occur if the user killed [page 693] the `vim` process), `vim` returns a nonzero exit status and the script executes the statements following `else`.

**select**

The `select` control structure (not available in `tcsh`) is based on the one found in the Korn Shell. It displays a menu, assigns a value to a variable based on the user's choice of items, and executes a series of commands. The `select` control structure has the following syntax:

```
select
varname
```
The `select` structure displays a menu of the `arg` items. If you omit the keyword `in` and the list of arguments, `select` uses the positional parameters in place of the `arg` items. The menu is formatted with numbers before each item. For example, a `select` structure that begins with

```
select fruit in apple banana blueberry kiwi orange watermelon STOP
```

displays the following menu:

1) apple       3) blueberry   5) orange      7) STOP
2) banana      4) kiwi        6) watermelon

The `select` structure uses the values of the `LINES` and `COLUMNS` variables to determine the size of the display. (`LINES` has a default value of 24; `COLUMNS` has a default value of 80.) With `COLUMNS` set to 20, the menu looks like this:

1) apple
2) banana
3) blueberry
4) kiwi
5) orange
6) watermelon
7) STOP

After displaying the menu `select` displays the value of `PS3`, the special `select` prompt. The default value of `PS3` is `?#` but you typically set `PS3` to a more meaningful value. When you enter a valid number (one in the menu range) in response to the `PS3` prompt, `select` sets `varname` to the argument corresponding to the number you entered. If you make an invalid entry, `varname` is set to null. Either way `select` stores your response in the keyword variable `REPLY` and then executes the `commands` between `do` and `done`. If you press `RETURN` without entering a choice, the shell redisplays the menu and the `PS3` prompt.

The `select` structure continues to issue the `PS3` prompt and execute the `commands` until something causes it to
exit typically a **break** or **exit** statement. A **break** statement exits from the loop and an **exit** statement exits from the script.

The following script illustrates the use of **select**:

```
$ cat fruit2
#!/bin/bash
PS3="Choose your favorite fruit from these possibilities: "]
select FRUIT in apple banana blueberry kiwi orange watermelon STOP
do
   if [ "$FRUIT" == "" ]; then
      echo -e "Invalid entry.\n"
      continue
   elif [ $FRUIT = STOP ]; then
      echo "Thanks for playing!"
      break
   fi
   echo "You chose $FRUIT as your favorite."
   echo -e "That is choice number $REPLY.\n"
done
$ fruit2
1) apple       3) blueberry   5) orange       7) STOP
2) banana      4) kiwi        6) watermelon
Choose your favorite fruit from these possibilities: 3
You chose blueberry as your favorite.
That is choice number 3.

Choose your favorite fruit from these possibilities: 99
Invalid entry.
```
Choose your favorite fruit from these possibilities: 7

Thanks for playing!

After setting the `PS3` prompt and establishing the menu with the `select` statement, `fruit2` executes the `commands` between `do` and `done`. If the user makes an invalid entry, the shell sets `varname ($FRUIT)` to a null value, so `fruit2` first tests whether `$FRUIT` is null. If it is, `echo` displays an error and `continue` causes the shell to redisplay the `PS3` prompt. If the entry is valid, the script tests whether the user wants to stop. If so, `echo` displays a message and `break` exits from the `select` structure (and from the script). If the user entered a valid response and does not want to stop, the script displays the name and number of the user's response. (See page 463 for information about the `\e` option to `echo`.)

**Here Document**

A Here document allows you to redirect input to a shell script from within the shell script itself. A Here document is so called because it is `here` immediately accessible in the shell script instead of `there`, perhaps in another file.

The following script, named `birthday`, contains a Here document. The two less than (`<<`) symbols in the first line indicate that a Here document follows. One or more characters that delimit the Here document follow the less than symbols; this example uses a plus sign. Whereas the opening delimiter must appear adjacent to the less than symbols, the closing delimiter must be on a line by itself. The shell sends everything between the two delimiters to the process as standard input. In the example it is as though you had redirected standard input to `grep` from a file, except that the file is embedded in the shell script:

```
$ cat birthday

grep -i "$1" <<+
Alex June 22
Barbara February 3
Darlene May 8
Helen March 13
Jenny January 23
Nancy June 26
+
$ birthday Jenny
Jenny January 23
$ birthday june
Alex June 22
```
When you run `birthday`, it lists all the Here document lines that contain the argument you called it with. In this case the first time `birthday` is run, it displays Jenny's birthday because it is called with an argument of `Jenny`. The second run displays all the birthdays in June. The `i` argument causes `grep's` search not to be case sensitive.
optional

The next script, named `bundle`,\(^2\) includes a clever use of a Here document. The `bundle` script is an elegant example of a script that creates a shell archive (shar) file. The script creates a file that is itself a shell script containing several other files as well as the code to re-create the original files:

```bash
$ cat bundle
#!/bin/bash
# bundle:  group files into distribution package

echo "# To unbundle, bash this file"
for i
do
echo "echo $i 1>&2"
echo "cat >$i <<'End of $i'"
cat $i
echo "End of $i"
done

Just as the shell does not treat special characters that occur in standard input of a shell script as special, so the shell does not treat the special characters that occur between the delimiters in a Here document as special.

As the following example shows, the output of `bundle` is a shell script, which is redirected to a file named `bothfiles`. It contains the contents of each file given as an argument to `bundle` (file1 and file2 in this case) inside a Here document. To extract the original files from `bothfiles`, you simply run it as an argument to a `bash` command. Before each Here document is a `cat` command that causes the Here document to be written to a new file when `bothfiles` is run:

```
$ cat file1
This is a file.
It contains two lines.
$ cat file2
This is another file.
```
It contains three lines.

$ bundle file1 file2 > bothfiles

$ cat bothfiles
# To unbundle, bash this file

echo file1 1>&2
cat >file1 <<'End of file1'
This is a file.
It contains two lines.
End of file1
echo file2 1>&2
cat >file2 <<'End of file2'
This is another file.
It contains three lines.
End of file2

In the next example, file1 and file2 are removed before bothfiles is run. The bothfiles script echoes the names of the files it creates as it creates them. The ls command then shows that bothfiles has re-created file1 and file2:

$ rm file1 file2

$ bash bothfiles

file1
file2

$ ls
bothfiles
file1
file2

file Descriptors

As discussed on page 260, before a process can read from or write to a file it must open that file. When a process opens a file, Linux associates a number (called a file descriptor) with the file. Each process has its own set of open files and its own file descriptors. After opening a file, a process reads from and writes to that file by referring to its file descriptor. When it no longer needs the file, the process closes the file, freeing the file descriptor.

A typical Linux process starts with three open files: standard input (file descriptor 0), standard output (file descriptor 1), and standard error (file descriptor 2). Often those are the only files the process needs. Recall that you redirect standard output with the symbol > or the symbol 1> and that you redirect standard error with the symbol 2>.

Although you can redirect other file descriptors, because file descriptors other than 0, 1, and 2 do not have any special conventional meaning, it is rarely useful to do so.

The exception is in programs that you write yourself, in which case you control the meaning of the file descriptors and can take advantage of redirection.

Opening a file descriptor

The Bourne Again Shell opens files using the exec builtin as follows:

```
exec  
n  >  outfile

exec  
m  <  infile
```

The first line opens outfile for output and holds it open, associating it with file descriptor n. The second line opens infile for input and holds it open, associating it with file descriptor m.

Duplicating a file descriptor

The <& token duplicates an input file descriptor; use >& to duplicate an output file descriptor. You can duplicate a file descriptor by making it refer to the same file as another open file descriptor, such as standard input or output. Use the following format to open or redirect file descriptor n as a duplicate of file descriptor m:

```
exec  
n  <&  m
```

Once you have opened a file, you can use it for input and output in two different ways. First, you can use I/O redirection on any command line, redirecting standard output to a file descriptor with >& n or redirecting standard input from a file descriptor with <& n. Second, you can use the read (page 487) and echo builtinS. If you invoke other commands, including functions (page 315), they inherit these open files and file descriptors. When you have
finished using a file, you can close it with

```
exec
n
<&
```

When you invoke the shell function in the next example, named mycp, with two arguments, it copies the file named by the first argument to the file named by the second argument. If you supply only one argument, the script copies the file named by the argument to standard output. If you invoke mycp with no arguments, it copies standard input to standard output.

**tip: A function is not a shell script**

The mycp example is a shell function; it will not work as you expect if you execute it as a shell script. (It will work: The function will be created in a very short-lived subshell, which is probably of little use.) You can enter this function from the keyboard. If you put the function in a file, you can run it as an argument to the . (dot) builtin (page 259). You can also put the function in a startup file if you want it to be always available (page 317).

```bash
function mycp ()
{
  case $# in
  0)
    # zero arguments
    # file descriptor 3 duplicates standard input
    # file descriptor 4 duplicates standard output
    exec 3<&0 4<&1
    ;;
  1)
    # one argument
    # open the file named by the argument for input
    # and associate it with file descriptor 3
    # file descriptor 4 duplicates standard output
    exec 3< $1 4<&1
  esac
}
```
The real work of this function is done in the line that begins with `cat`. The rest of the script arranges for file descriptors 3 and 4, which are the input and output of the `cat` command, to be associated with the appropriate files.
optional

The next program takes two filenames on the command line, sorts both, and sends the output to temporary files. The program then merges the sorted files to standard output, preceding each line by a number that indicates which file it came from.

$ cat sortmerg

#!/bin/bash
usage ()
{
if [ $# -ne 2 ]; then
    echo "Usage: $0 file1 file2" 2>&1
    exit 1
    fi
}
# Default temporary directory
: ${TEMPDIR:=/tmp}

# Check argument count
usage "$@"

# Set up temporary files for sorting
file1=${TEMPDIR}/$$.file1
file2=${TEMPDIR}/$$.file2

# Sort
sort $1 > $file1
sort $2 > $file2
# Open $file1 and $file2 for reading. Use file descriptors 3 and 4.
exec 3<$file1
exec 4<$file2

# Read the first line from each file to figure out how to start.
read Line1 <&3
status1=$?
read Line2 <&4
status2=$?

# Strategy: while there is still input left in both files:
#   Output the line that should come first.
#   Read a new line from the file that line came from.
while [ $status1 -eq 0 -a $status2 -eq 0 ]
do
    if [[ "$Line2" > "$Line1" ]]; then
        echo -e "1.\t$Line1"
        read -u3 Line1
        status1=$?
    else
        echo -e "2.\t$Line2"
        read -u4 Line2
        status2=$?
    fi
done
# Now one of the files is at end-of-file.
# Read from each file until the end.
# First file1:
while [ $status1 -eq 0 ]
  do
    echo -e "1.\t$Line1"
    read Line1 <&3
    status1=$?
  done
# Next file2:
while [[ $status2 -eq 0 ]]
  do
    echo -e "2.\t$Line2"
    read Line2 <&4
    status2=$?
  done
# Close and remove both input files
exec 3<&- 4<&-
rm -f $file1 $file2
exit 0
Parameters And Variables

Shell parameters and variables were introduced on page 277. This section adds to the previous coverage with a discussion of array variables, global versus local variables, special and positional parameters, and expanding null and unset variables.

Array Variables

The Bourne Again Shell supports one-dimensional array variables. The subscripts are integers with zero-based indexing (i.e., the first element of the array has the subscript 0). The following format declares and assigns values to an array:

```
name=(element1 element2 ...)  
```

The following example assigns four values to the array NAMES:

```
$ NAMES=(max helen sam zach)  
```

You reference a single element of an array as follows:

```
$ echo ${NAMES[2]}  
sam  
```

The subscripts [*] and [@] both extract the entire array but work differently when used within double quotation marks. An @ produces an array that is a duplicate of the original array; an * produces a single element of an array (or a plain variable) that holds all the elements of the array separated by the first character in IFS (normally a SPACE). In the following example, the array A is filled with the elements of the NAMES variable using an *, and B is filled using an @. The declare builtin with the -a option displays the values of the arrays (and reminds you that bash uses zero-based indexing for arrays):

```
$ A="${NAMES[*]}"
$ B="${NAMES[@]}"

$ declare -a
declare -a A='([0]="max helen sam zach")'
...
```
From the output of `declare`, you can see that `NAMES` and `B` have multiple elements. In contrast, `A`, which was assigned its value with an `*` within double quotation marks, has only one element: `A` has all its elements enclosed between double quotation marks.

In the next example, `echo` attempts to display element 1 of array `A`. Nothing is displayed because `A` has only one element and that element has an index of 0. Element 0 of array `A` holds all four names. Element 1 of `B` holds the second item in the array and element 0 holds the first item.

```
$ echo ${A[1]}

$ echo ${A[0]}
max helen sam zach

$ echo ${B[1]}
helen

$ echo ${B[0]}
max
```

You can apply the `#${name[*]}` operator to array variables, returning the number of elements in the array:

```
$ echo ${#NAMES[*]}
4
```

The same operator, when given the index of an element of an array in place of `*`, returns the length of the element:

```
$ echo ${#NAMES[1]}
5
```

You can use subscripts on the left side of an assignment statement to replace selected elements of the array:

```
$ NAMES[1]=alex

$ echo ${NAMES[*]}
max alex sam zach
```

Locality of Variables
By default variables are local to the process in which they are declared. Thus a shell script does not have access to variables declared in your login shell unless you explicitly make the variables available (global). Under bash, `export` makes a variable available to child processes. Under tcsh, `setenv` (page 356) assigns a value to a variable and makes it available to child processes. The examples in this section use the bash syntax but the theory applies to both shells.

Once you use the `export` builtin with a variable name as an argument, the shell places the value of the variable in the calling environment of child processes. This *call by value* gives each child process a copy of the variable for its own use.

The following `extest1` shell script assigns a value of *american* to the variable named `cheese` and then displays its filename (`extest1`) and the value of `cheese`. The `extest1` script then calls `subtest`, which attempts to display the same information. Next `subtest` declares a `cheese` variable and displays its value. When `subtest` finishes, it returns control to the parent process, which is executing `extest1`. At this point `extest1` again displays the value of the original `cheese` variable.

```bash
$ cat extest1
cheese=american
echo "extest1 1: $cheese"
subtest
echo "extest1 2: $cheese"
$ cat subtest
echo "subtest 1: $cheese"
cheese=swiss
echo "subtest 2: $cheese"
$ extest1
extest1 1: american
subtest 1:
subtest 2: swiss
extest1 2: american
```

The `subtest` script never receives the value of `cheese` from `extest1`, and `extest1` never loses the value. Unlike in the real world, a child can never affect its parent's attributes. When a process attempts to display the value of a variable that has not been declared, as is the case with `subtest`, the process displays nothing; the value of an undeclared variable is that of a null string.

The following `extest2` script is the same as `extest1` except that it uses `export` to make `cheese` available to the `subtest` script:
Here the child process inherits the value of `cheese` as `american` and, after displaying this value, changes its copy to `swiss`. When control is returned to the parent, the parent's copy of `cheese` retains its original value: `american`.

An `export` builtin can optionally include an assignment:

```bash
export cheese=american
```

The preceding statement is equivalent to the following two statements:

```bash
cheese=american
export cheese
```

Although it is rarely done, you can export a variable before you assign a value to it. You do not need to export an already-exported variable a second time after you change its value. For example, you do not usually need to export `PATH` when you assign a value to it in `~/.bash_profile` because it is typically exported in the `/etc/profile` global startup file.

**Functions**

Because functions run in the same environment as the shell that calls them, variables are implicitly shared by a shell and a function it calls.

```bash
$ function nam () {
```
In the preceding example, the `myname` variable is set to `sam` in the interactive shell. Then the `nam` function is called. It displays the value of `myname` it has (`sam`) and sets `myname` to `zach`. The final `echo` shows that, in the interactive shell, the value of `myname` has been changed to `zach`.

**Function local variables**

Local variables are helpful in a function written for general use. Because the function is called by many scripts that may be written by different programmers, you need to make sure that the names of the variables used within the function do not interact with variables of the same name in the programs that call the function. Local variables eliminate this problem. When used within a function, the `typeset` builtin declares a variable to be local to the function it is defined in.

The next example shows the use of a local variable in a function. It uses two variables named `count`. The first is declared and assigned a value of 10 in the interactive shell. Its value never changes, as `echo` verifies after `count_down` is run. The other `count` is declared, using `typeset`, to be local to the function. Its value, which is unknown outside the function, ranges from 4 to 1, as the `echo` command within the function confirms.

The example shows the function being entered from the keyboard; it is not a shell script. (See the tip "A function is not a shell script" on page 471).

```bash
$ function count_down () {

> echo $myname
> myname=zach
> }

$ myname=sam
$ nam
sam
$ echo $myname
zach

> typeset count
> count=$1
> while [ $count -gt 0 ]
> do
> echo $count
> count=$((count-1))
> done
```

```bash
$ echo $myname
zach
```
> echo "$count..."
> ((count=count-1))
> sleep 1
> done
> echo "Blast Off."
> }
$ count=10
$ count_down 4

4...
3...
2...
1...
Blast Off!

$ echo $count
10

The $((count=count-1)) assignment is enclosed between double parentheses, which cause the shell to perform an arithmetic evaluation (page 501). Within the double parentheses you can reference shell variables without the leading dollar sign ($).

Special Parameters

Special parameters enable you to access useful values pertaining to command line arguments and the execution of shell commands. You reference a shell special parameter by preceding a special character with a dollar sign ($). As with positional parameters, it is not possible to modify the value of a special parameter by assignment.

$$: PID Number

The shell stores in the $$ parameter the PID number of the process that is executing it. In the following interaction, echo displays the value of this variable and the ps utility confirms its value. Both commands show that the shell has a PID number of 5209:

$ echo $$
5209
Because `echo` is built into the shell, the shell does not have to create another process when you give an `echo` command. However, the results are the same whether `echo` is a builtin or not, because the shell substitutes the value of `$$` before it forks a new process to run a command. Try using the `echo` utility (`/bin/echo`), which is run by another process, and see what happens. In the following example, the shell substitutes the value of `$$` and passes that value to `cp` as a prefix for a filename:

```
$ echo $$
8232
$ cp memo $$.memo
$ ls
8232.memo memo
```

Incorporating a PID number in a filename is useful for creating unique filenames when the meanings of the names do not matter; it is often used in shell scripts for creating names of temporary files. When two people are running the same shell script, these unique filenames keep them from inadvertently sharing the same temporary file.

The following example demonstrates that the shell creates a new shell process when it runs a shell script. The `id2` script displays the PID number of the process running it (not the process that called it; the substitution for `$$` is performed by the shell that is forked to run `id2`):

```
$ cat id2
echo "$0 PID= $$"
$ echo $$
8232
$ id2
./id2 PID= 8362
$ echo $$
8232
```
The first `echo` displays the PID number of the interactive shell. Then `id2` displays its name ($0) and the PID of the subshell that it is running in. The last `echo` shows that the PID number of the interactive shell has not changed.

$!

The value of the PID number of the last process that you ran in the background is stored in $! (not available in tcsh). The following example executes `sleep` as a background task and uses `echo` to display the value of $!:

```
$ sleep 60 &
8376

$ echo $!
8376
```

`$?: Exit Status`

When a process stops executing for any reason, it returns an exit status to the parent process. The exit status is also referred to as a condition code or a return code. The $? ($status under tcsh) variable stores the exit status of the last command.

By convention a nonzero exit status represents a false value and means that the command failed. A zero is true and indicates that the command was successful. In the following example, the first `ls` command succeeds and the second fails:

```
$ ls es
es

$ echo $?
0

$ ls xxx
ls: xxx: No such file or directory

$ echo $?
1
```

You can specify the exit status that a shell script returns by using the `exit` builtin, followed by a number, to terminate the script. If you do not use `exit` with a number to terminate a script, the exit status of the script is that of the last command the script ran.
$ cat es

echo This program returns an exit status of 7.
exit 7
$ es

This program returns an exit status of 7.
$ echo $?
7
$ echo $?
0

The es shell script displays a message and terminates execution with an exit command that returns an exit status of 7, the user-defined exit status in this script. The first echo then displays the value of the exit status of es. The second echo displays the value of the exit status of the first echo. The value is 0 because the first echo was successful.

Positional Parameters

The positional parameters comprise the command name and command line arguments. They are called positional because within a shell script, you refer to them by their position on the command line. Only the set builtin (page 484) allows you to change the values of positional parameters with one exception: You cannot change the value of the command name from within a script. The tcsh set builtin does not change the values of positional parameters.

#$: Number of Command Line Arguments

The $# parameter holds the number of arguments on the command line (positional parameters), not counting the command itself:

$ cat num_args

echo "This script was called with $# arguments."
$ num_args sam max zach

This script was called with 3 arguments.

$0: Name of the Calling Program

The shell stores the name of the command you used to call a program in parameter $0. This parameter is numbered
zero because it appears before the first argument on the command line:

$ cat abc
echo "The command used to run this script is $0"

$ abc
The command used to run this script is ./abc

$ /home/sam/abc
The command used to run this script is /home/sam/abc

The preceding shell script uses `echo` to verify the name of the script you are executing. You can use the `basename` utility and command substitution to extract and display the simple filename of the command:

$ cat abc2
echo "The command used to run this script is $(basename $0)"

$ /home/sam/abc2
The command used to run this script is abc2

$1 % $n: Command Line Arguments

The first argument on the command line is represented by parameter $1, the second argument by $2, and so on up to $n. For values of $n over 9, the number must be enclosed within braces. For example, the twelfth command line argument is represented by ${12}. The following script displays positional parameters that hold command line arguments:

$ cat display_5args

echo First 5 arguments are $1 $2 $3 $4 $5

$ display_5args jenny alex helen
First 5 arguments are jenny alex helen

The `display_5args` script displays the first five command line arguments. The shell assigns a null value to each parameter that represents an argument that is not present on the command line. Thus the $4 and $5 variables have null values in this example.
$*

The $* variable represents all the command line arguments, as the `display_all` program demonstrates:

```bash
$ cat display_all
echo All arguments are $*
```

```bash
$ display_all a b c d e f g h i j k l m n o p
All arguments are a b c d e f g h i j k l m n o p
```

Enclose references to positional parameters between double quotation marks. The quotation marks are particularly important when you are using positional parameters as arguments to commands. Without double quotation marks, a positional parameter that is not set or that has a null value disappears:

```bash
$ cat showargs
echo "$0 was called with $# arguments, the first is :$1:."
```

```bash
$ showargs a b c
./showargs was called with 3 arguments, the first is :a:.
$ echo $xx
```

```bash
$ showargs $xx a b c
./showargs was called with 3 arguments, the first is :a:.
$ showargs "$xx" a b c
./showargs was called with 4 arguments, the first is ::.
```

The `showargs` script displays the number of arguments ($#) followed by the value of the first argument enclosed between colons. The preceding example first calls `showargs` with three simple arguments. Next the `echo` command demonstrates that the `$xx` variable, which is not set, has a null value. In the final two calls to `showargs`, the first argument is `$xx`. In the first case the command line becomes `showargs a b c`; the shell passes `showargs` three arguments. In the second case the command line becomes `showargs "$xx" a b c`, which results in calling `showargs` with four arguments. The difference in the two calls to `showargs` illustrates a subtle potential problem that you should keep in mind when using positional parameters that may not be set or that may have a null value.

"$*" versus "$@"
The $* and $@ parameters work the same way except when they are enclosed within double quotation marks. Using "$*" yields a single argument (with SPACEs or the value of IFS [page 288] between the positional parameters), whereas "$@" produces a list wherein each positional parameter is a separate argument. This difference typically makes "$@" more useful than "$*" in shell scripts.

The following scripts help to explain the difference between these two special parameters. In the second line of both scripts, the single quotation marks keep the shell from interpreting the enclosed special characters so they can be displayed as themselves. The bb1 script shows that set "$*" assigns multiple arguments to the first command line parameter:

    $ cat bb1
    set "$*"
    echo $# parameters with '"$*"'
    echo 1: $1
    echo 2: $2
    echo 3: $3
    $ bb1 a b c
    1 parameters with "$*"
    1: a b c
    2:
    3:

The bb2 script shows that set "$@" assigns each argument to a different command line parameter:

    $ cat bb2
    set "$@
    echo $# parameters with '"$@"'
    echo 1: $1
    echo 2: $2
    echo 3: $3
    $ bb2 a b c
    3 parameters with "$@"
shift: Promotes Command Line Arguments

The shift builtin promotes each command line argument. The first argument (which was $1) is discarded. The second argument (which was $2) becomes the first argument (now $1), the third becomes the second, and so on. Because no "unshift" command exists, you cannot bring back arguments that have been discarded. An optional argument to shift specifies the number of positions to shift (and the number of arguments to discard); the default is 1.

The following demo_shift script is called with three arguments. Double quotation marks around the arguments to echo preserve the spacing of the output. The program displays the arguments and shifts them repeatedly until there are no more arguments left to shift:

$ cat demo_shift

```
echo "arg1= $1    arg2= $2    arg3= $3"
shift
echo "arg1= $1    arg2= $2    arg3= $3"
shift
echo "arg1= $1    arg2= $2    arg3= $3"
shift
echo "arg1= $1    arg2= $2    arg3= $3"
shift
$ demo_shift alice helen jenny

arg1= alice    arg2= helen    arg3= jenny
arg1= helen    arg2= jenny    arg3=
arg1= jenny    arg2=    arg3=
arg1=    arg2=    arg3=
```

Repeatedly using shift is a convenient way to loop over all the command line arguments in shell scripts that expect an arbitrary number of arguments. See page 442 for a shell script that uses shift.
set: Initializes Command Line Arguments

When you call the `set` builtin with one or more arguments, it assigns the values of the arguments to the positional parameters, starting with `$1` (not available in `tcsh`). The following script uses `set` to assign values to the positional parameters `$1`, `$2`, and `$3`:

```bash
$ cat set_it
set this is it
echo $3 $2 $1
$ set_it
it is this
```

Combining command substitution (page 329) with the `set` builtin is a convenient way to get standard output of a command in a form that can be easily manipulated in a shell script. The following script shows how to use `date` and `set` to provide the date in a useful format. The first command shows the output of `date`. Then `cat` displays the contents of the `dateset` script. The first command in this script uses command substitution to set the positional parameters to the output of the `date` utility. The next command, `echo *`, displays all positional parameters resulting from the previous `set`. Subsequent commands display the values of parameters `$1`, `$2`, `$3`, and `$4`. The final command displays the date in a format you can use in a letter or report:

```bash
$ date
Wed Jan  5 23:39:18 PST 2005
$ cat dateset
set $(date)
echo *

echo

echo "Argument 1: $1"

echo "Argument 2: $2"

echo "Argument 3: $3"

echo "Argument 6: $6"

echo

echo "$2 $3, $6"
```
$ dataset

Wed Jan 5 23:39:25 PST 2005

Argument 1: Wed
Argument 2: Jan
Argument 3: 5
Argument 6: 2005

Jan 5, 2005

You can also use the +format argument to date (page 630) to modify the format of its output.

When used without any arguments, set displays a list of the shell variables that are set, including user-created variables and keyword variables. Under bash, this list is the same as that displayed by declare and typeset when they are called without any arguments.

The set builtin also accepts options that let you customize the behavior of the shell (not available in tcsh). For more information refer to "set ±o: Turns Shell Features On and Off" on page 319.

Expanding Null and Unset Variables

The expression ${name} (or just $name if it is not ambiguous) expands to the value of the name variable. If name is null or not set, bash expands $name to a null string. The Bourne Again Shell provides the following alternatives to accepting the expanded null string as the value of the variable:

- Use a default value for the variable.
- Use a default value and assign that value to the variable.
- Display an error.

You can choose one of these alternatives by using a modifier with the variable name. In addition, you can use set ±o nounset (page 321) to cause bash to display an error and exit from a script whenever an unset variable is referenced.

:  Uses a Default Value

The := modifier uses a default value in place of a null or unset variable while allowing a nonnull variable to represent itself:

$ {name:=default}
The shell interprets `:=` as "If \texttt{name} is null or unset, expand \texttt{default} and use the expanded value in place of \texttt{name}; else use \texttt{name}." The following command lists the contents of the directory named by the \texttt{LIT} variable. If \texttt{LIT} is null or unset, it lists the contents of \texttt{/home/alex/literature}:

\begin{verbatim}
$ ls ${LIT:-/home/alex/literature}
\end{verbatim}

The default can itself have variable references that are expanded:

\begin{verbatim}
$ ls ${LIT:-$HOME/literature}
\end{verbatim}

\textbf{:= Assigns a Default Value}

The \texttt{:=} modifier does not change the value of a variable. You may want to change the value of a null or unset variable to its default in a script, however. You can do so with the \texttt{:=} modifier:

\begin{verbatim}
{name:=default}
\end{verbatim}

The shell expands the expression \texttt{$\{name:=default\}$} in the same manner as it expands \texttt{$\{name::default\}$} but also sets the value of \texttt{name} to the expanded value of \texttt{default}. If a script contains a line such as the following and \texttt{LIT} is unset or null at the time this line is executed, \texttt{LIT} is assigned the value \texttt{/home/alex/literature}:

\begin{verbatim}
$ ls ${LIT:=/home/alex/literature}
\end{verbatim}

\textbf{builtin}

Shell scripts frequently start with the \texttt{:} (colon) builtin followed on the same line by the \texttt{:=} expansion modifier to set any variables that may be null or unset. The \texttt{:} builtin evaluates each token in the remainder of the command line but does not execute any commands. Without the leading colon (\texttt{:}), the shell evaluates and attempts to execute the "command" that results from the evaluation.

Use the following syntax to set a default for a null or unset variable in a shell script (there is a \texttt{SPACE} following the first colon):

\begin{verbatim}
: ${name:=default}
\end{verbatim}

When a script needs a directory for temporary files and uses the value of \texttt{TEMPDIR} for the name of this directory, the following line makes \texttt{TEMPDIR} default to \texttt{/tmp}:

\begin{verbatim}
: ${TEMPDIR:=/tmp}
\end{verbatim}
Displays An Error Message

Sometimes a script needs the value of a variable but you cannot supply a reasonable default at the time you write the script. If the variable is null or unset, the `?:` modifier causes the script to display an error message and terminate with an exit status of 1:

```
${name:?message}
```

You must quote `message` if it contains SPACEs. If you omit `message`, the shell displays the default error message (`parameter null or not set`). Interactive shells do not exit when you use `?:`. In the following command, `TESTDIR` is not set so the shell displays on standard error the expanded value of the string following `?:`. In this case the string includes command substitution for `date`, with the `%T` format being followed by the string `error, variable not set`.

```
cd ${TESTDIR:?$(date +%T) error, variable not set.}
```

```
```
Built-in Commands

Built-in commands were introduced in Chapter 5. Commands that are built into a shell do not fork a new process when you execute them. This section discusses the `type`, `read`, `exec`, `trap`, `kill`, and `getopts` builtins and concludes with Table 11-6 on page 500, which lists many bash builtins. See Table 9-10 on page 377 for a list of tcsh builtins.

**type: Displays Information About a Command**

The `type` builtin (use `which` under tcsh) provides information about a command:

```
$ type cat echo who if lt

cat is hashed (/bin/cat)

echo is a shell builtin

who is /usr/bin/who

if is a shell keyword

lt is aliased to 'ls -ltrh | tail'
```

The preceding output shows the files that would be executed if you gave `cat` or `who` as a command. Because `cat` has already been called from the current shell, it is in the hash table (page 878) and `type` reports that `cat` is hashed. The output also shows that a call to `echo` runs the `echo` builtin, `if` is a keyword, and `lt` is an alias.

**read: Accepts User Input**

When you begin writing shell scripts, you soon realize that one of the most common tasks for user-created variables is storing information a user enters in response to a prompt. Using `read`, scripts can accept input from the user and store that input in variables. See page 361 for information about reading user input under tcsh. The `read` builtin reads one line from standard input and assigns the words on the line to one or more variables:

```
$ cat read1

echo -n "Go ahead: "

read firstline

echo "You entered: $firstline"

$ read1

Go ahead: This is a line.

You entered: This is a line.
```
The first line of the `read1` script uses `echo` to prompt you to enter a line of text. The `-n` option suppresses the following NEWLINE, allowing you to enter a line of text on the same line as the prompt. The second line reads the text into the variable `firstline`. The third line verifies the action of `read` by displaying the value of `firstline`. The variable is quoted (along with the text string) in this example because you, as the script writer, cannot anticipate which characters the user might enter in response to the prompt. Consider what would happen if the variable were not quoted and the user entered `*` in response to the prompt:

```
$ cat read1_no_quote
echo -n "Go ahead: "
read firstline
echo You entered: $firstline
$ read1_no_quote
Go ahead: *
You entered: read1 read1_no_quote script.1
$ ls
read1  read1_no_quote  script.1
```

The `ls` command lists the same words as the script, demonstrating that the shell expands the asterisk into a list of files in the working directory. When the variable `$firstline` is surrounded by double quotation marks, the shell does not expand the asterisk. Thus the `read1` script behaves correctly:

```
$ read1
Go ahead: *
You entered: *
```

If you want the shell to interpret the special meanings of special characters, do not use quotation marks.

**REPLY**

The `read` builtin has features that can make it easier to use. When you do not specify a variable to receive `read`'s input, `bash` puts the input into the variable named `REPLY`. You can use the `-p` option to prompt the user instead of using a separate `echo` command. The following `read1a` script performs exactly the same task as `read1`:

```
$ cat read1a
read -p "Go ahead: 
```
echo "You entered: $REPLY"

The **read2** script prompts for a command line and reads the user's response into the variable **cmd**. The script then attempts to execute the command line that results from the expansion of the **cmd** variable:

```
$ cat read2
read -p "Enter a command: " cmd
$cmd
echo "Thanks"
```

In the following example, **read2** reads a command line that calls the **echo** builtin. The shell executes the command and then displays **Thanks**. Next **read2** reads a command line that executes the **who** utility:

```
$ read2
Enter a command: echo Please display this message.
Please display this message.
Thanks
$ read2
Enter a command: who
alex pts/4 Jun 17 07:50 (:0.0)
scott pts/12 Jun 17 11:54 (bravo.example.com)
Thanks
```

If **cmd** does not expand into a valid command line, the shell issues an error message:

```
$ read2
Enter a command: xxx
./read2: line 2: xxx: command not found
Thanks
```

The **read3** script reads values into three variables. The **read** builtin assigns one word (a sequence of nonblank characters) to each variable:
$ cat read3

read -p "Enter something: " word1 word2 word3

echo "Word 1 is: $word1"

echo "Word 2 is: $word2"

echo "Word 3 is: $word3"

$ read3

Enter something: this is something

Word 1 is: this

Word 2 is: is

Word 3 is: something

When you enter more words than `read` has variables, `read` assigns one word to each variable, with all leftover words going to the last variable. Both `read1` and `read2` assigned the first word and all leftover words to the one variable they each had to work with. In the following example, `read` accepts five words into three variables, assigning the first word to the first variable, the second word to the second variable, and the third through fifth words to the third variable:

$ read3

Enter something: this is something else, really.

Word 1 is: this

Word 2 is: is

Word 3 is: something else, really.

Table 11-4 lists some of the options supported by the `read` builtin.

Table 11-4. read options

</tbody>
</table>

```
read u4 arg1 arg2
```

is equivalent to

```
read arg1 arg2 <&4
```

See "File Descriptors" (page 470) for a discussion of redirection and file descriptors.

The `read` builtin returns an exit status of 0 if it successfully reads any data. It has a nonzero exit status when it reaches the EOF (end of file). The following example runs a `while` loop from the command line. It takes its input from the `names` file and terminates after reading the last line from `names`.

```
$ cat names
Alice Jones
Robert Smith
Alice Paulson
John Q. Public

$ while read first rest
> do
> echo $rest, $first
> done < names
Jones, Alice
Smith, Robert
Paulson, Alice
```
Q. Public, John

$ 

The placement of the redirection symbol (<) for the while structure is critical. It is important that you place the redirection symbol at the done statement and not at the call to read.
Each time you redirect input, the shell opens the input file and repositions the read pointer at the start of the file:

```bash
$ read line1 < names; echo $line1; read line2 < names; echo $line2
Alice Jones
Alice Jones
```

Here each `read` opens `names` and starts at the beginning of the `names` file. In the following example, `names` is opened once, as standard input of the subshell created by the parentheses. Each `read` then reads successive lines of standard input.

```bash
$ (read line1; echo $line1; read line2; echo $line2) < names
Alice Jones
Robert Smith
```

Another way to get the same effect is to open the input file with `exec` and hold it open (refer to "File Descriptors" on page 470):

```bash
$ exec 3< names
$ read -u3 line1; echo $line1; read -u3 line2; echo $line2
Alice Jones
Robert Smith
$ exec 3<&-
```

**exec**: Executes a Command

The `exec` builtin (not available in `tcsh`) has two primary purposes: to run a command without creating a new process and to redirect a file descriptor—including standard input, output, or error—if of a shell script from within the script (page 470). When the shell executes a command that is not built into the shell, it typically creates a new process. The new process inherits environment (global or exported) variables from its parent but does not inherit variables that are not exported by the parent. (For more information refer to "Locality of Variables" on page 475.) In contrast, `exec` executes a command in place of (overlays) the current process.
**exec** versus . (dot)

Insofar as **exec** runs a command in the environment of the original process, it is similar to the . (dot) command (page 259). However, unlike the . command, which can run only shell scripts, **exec** can run both scripts and compiled programs. Also, whereas the . command returns control to the original script when it finishes running, **exec** does not. Finally, the . command gives the new program access to local variables, whereas **exec** does not.

**exec runs a command**

The **exec** builtin used for running a command has the following syntax:

```
exec
c  ommand  rguements
```

**exec does not return control**

Because the shell does not create a new process when you use **exec**, the command runs more quickly. However, because **exec** does not return control to the original program, it can be used only as the last command that you want to run in a script. The following script shows that control is not returned to the script:

```
$ cat exec_demo
who
eexec  date
echo "This line is never displayed."
$ exec_demo
jenny pts/7 May 30 7:05 (bravo.example.com)
hls pts/1 May 30 6:59 (:0.0)
Mon May 30 11:42:56 PDT 2005
```

The next example, a modified version of the **out** script (page 442), uses **exec** to execute the final command the script runs. Because **out** runs either **cat** or **less** and then terminates, the new version, named **out2**, uses **exec** with both **cat** and **less**:

```
$ cat out2
if [ $# -eq 0 ]
   then
```
echo "Usage: out2 [-v] filenames" 1>&2
exit 1
fi
if [ "$1" = "-v" ]
then
    shift
    exec less "$@
else
    exec cat -- "$@
fi

exec redirects input and output

The second major use of exec is to redirect a file descriptor—including standard input, output, or error—from within a script. The next command causes all subsequent input to a script that would have come from standard input to come from the file named infile:

exec < infile

Similarly the following command redirects standard output and standard error to outfile and errfile, respectively:

exec > outfile 2> errfile

When you use exec in this manner, the current process is not replaced with a new process, and exec can be followed by other commands in the script.

/dev/tty

When you redirect the output from a script to a file, you must make sure that the user sees any prompts the script displays. The /dev/tty device is a pseudonym for the screen the user is working on; you can use this device to refer to the user's screen without knowing which device it is. (The tty utility displays the name of the device you are using.) By redirecting the output from a script to /dev/tty, you ensure that prompts and messages go to the user's terminal, regardless of which terminal the user is logged in on. Messages sent to /dev/tty are also not diverted if standard output and standard error from the script are redirected.

The to_screen1 script sends output to three places: standard output, standard error, and the user's screen. When it is run with standard output and standard error redirected, to_screen1 still displays the message sent to /dev/tty on the
user's screen. The `out` and `err` files hold the output sent to standard output and standard error.

```
$ cat to_screen1
echo "message to standard output"
echo "message to standard error" 1>&2
echo "message to the user" > /dev/tty

$ to_screen1 > out 2> err
message to the user
$ cat out
message to standard output
$ cat err
message to standard error
```

The following command redirects the output from a script to the user's screen:

```
exec > /dev/tty
```

Putting this command at the beginning of the previous script changes where the output goes. In `to_screen2`, `exec` redirects standard output to the user's screen so the `> /dev/tty` is superfluous. Following the `exec` command, all output sent to standard output goes to `/dev/tty` (the screen). Output to standard error is not affected.

```
$ cat to_screen2
exec > /dev/tty
echo "message to standard output"
echo "message to standard error" 1>&2
echo "message to the user" > /dev/tty

$ to_screen2 > out 2> err
message to standard output
message to the user
```
One disadvantage of using `exec` to redirect the output to `/dev/tty` is that all subsequent output is redirected unless you use `exec` again in the script.

You can also redirect the input to `read` (standard input) so that it comes from `/dev/tty` (the keyboard):

```bash
read name < /dev/tty
```

or

```bash
exec < /dev/tty
```

**trap: Catches a Signal**

A **signal** is a report to a process about a condition. Linux uses signals to report interrupts generated by the user (for example, pressing the interrupt key) as well as bad system calls, broken pipes, illegal instructions, and other conditions. The `TRap` builtin (tcsh uses `onintr`) catches, or traps, one or more signals, allowing you to direct the actions a script takes when it receives a specified signal.

This discussion covers six signals that are significant when you work with shell scripts. Table 11-5 lists these signals, the signal numbers that systems often ascribe to them, and the conditions that usually generate each signal. Give the command `kill [l], trap [l], or man 7 signal` for a list of signal names.

When it traps a signal, a script takes whatever action you specify: It can remove files or finish any other processing as needed, display a message, terminate execution immediately, or ignore the signal. If you do not use `trap` in a script, any of the six actual signals listed in Table 11-5 (not EXIT, DEBUG, or ERR) terminates the script. Because a process cannot trap a KILL signal, you can use `kill KILL` (or `kill 9`) as a last resort to terminate a script or any other process. (See page 497 for more information on `kill`.)

The `TRap` command has the following syntax:

```
trap ['commands'] [signal]
```

The optional `commands` part specifies the commands that the shell executes when it catches one of the signals specified by `signal`. The `signal` can be a signal name or number—for example, INT or 2. If `commands` is not present, `trap` resets the trap to its initial condition, which is usually to exit from the script.

The `trap` builtin does not require single quotation marks around `commands` as shown in the preceding syntax, but it is a good practice to use them. The single quotation marks cause shell variables within the `commands` to be expanded when the signal occurs, not when the shell evaluates the arguments to `TRap`. Even if you do not use any shell variables in the `commands`, you need to enclose any command that takes arguments within either single or double quotation marks. Quoting the `commands` causes the shell to pass to `trap` the entire command as a single argument.

After executing the `commands`, the shell resumes executing the script where it left off. If you want `trap` to prevent a script from exiting when it receives a signal but not to run any commands explicitly, you can specify a null
(empty) **commands** string, as shown in the **locktty** script (page 458). The following command traps signal number 15 after which the script continues.

```
trap '' 15
```

The following script demonstrates how the **TRap** builtin can catch the terminal interrupt signal (2). You can use SIGINT, INT, or 2 to specify this signal. The script returns an exit status of 1:

```
$ cat inter
#!/bin/bash
trap 'echo PROGRAM INTERRUPTED; exit 1' INT
while true
do
    echo "Program running."
    sleep 1
done
$ inter
Program running.
Program running.
Program running.
CONTROL-C
PROGRAM INTERRUPTED
$

: (null) builtin

The second line of **inter** sets up a trap for the terminal interrupt signal using INT. When **trap** catches the signal, the shell executes the two commands between the single quotation marks in the **trap** command. The **echo** builtin displays the message **PROGRAM INTERRUPTED**, **exit** terminates the shell running the script, and the parent shell displays a prompt. If **exit** were not there, the shell would return control to the **while** loop after displaying the message. The **while** loop repeats continuously until the script receives a signal because the **true** utility always returns a **true** exit status. In place of **true** you can use the : (null) builtin, which is written as a colon and always returns a 0 (**true**) status.
The `trap` builtin frequently removes temporary files when a script is terminated prematurely so that the files are not left to clutter the filesystem. The following shell script, named `addbanner`, uses two `traps` to remove a temporary file when the script terminates normally or owing to a hangup, software interrupt, quit, or software termination signal:

```
$ cat addbanner

#!/bin/bash

script=$(basename $0)

if [ ! -r "$HOME/banner" ]
  then
    echo "$script: need readable $HOME/banner file" 1>&2
    exit 1
fi

trap 'exit 1' 1 2 3 15
trap 'rm /tmp/$$.script 2> /dev/null' 0

for file
  do
    if [ -r "$file" -a -w "$file" ]
      then
        cat $HOME/banner $file > /tmp/$$.script
        cp /tmp/$$.script $file
        echo "$script: banner added to $file" 1>&2
      else
        echo "$script: need read and write permission for $file" 1>&2
  fi
```
When called with one or more filename arguments, `addbanner` loops through the files, adding a header to the top of each. This script is useful when you use a standard format at the top of your documents, such as a standard layout for memos, or when you want to add a standard header to shell scripts. The header is kept in a file named `~/banner`. Because `addbanner` uses the `HOME` variable, which contains the pathname of the user’s home directory, the script can be used by several users without modification. If Alex had written the script with `/home/alex` in place of `$HOME` and then given the script to Jenny, either she would have had to change it or `addbanner` would have used Alex’s `banner` file when Jenny ran it (assuming Jenny had read permission for the file).

The first `trap` in `addbanner` causes it to exit with a status of 1 when it receives a hangup, software interrupt (terminal interrupt or quit signal), or software termination signal. The second `TRap` uses a 0 in place of `signal-number`, which causes `trap` to execute its command argument whenever the script exits because it receives an `exit` command or reaches its end. Together these `trap`s remove a temporary file whether the script terminates normally or prematurely. Standard error of the second `trap` is sent to `/dev/null` for cases in which `trap` attempts to remove a nonexistent temporary file. In those cases `rm` sends an error message to standard error; because standard error is redirected, the user does not see this message.

See page 458 for another example that uses `TRap`.

**kill: Aborts a Process**

The `kill` builtin sends a signal to a process or job. The `kill` command has the following syntax:

```
kill [\[-\]]
    signal
            ]
PID
```

where `signal` is the signal name or number (for example, INT or 2) and `PID` is the process identification number of the process that is to receive the signal. You can specify a job number (page 125) as `%n` in place of `PID`. If you omit `signal`, `kill` sends a TERM (software termination, number 15) signal. For more information on signal names and numbers see Table 11-5 on page 494.

The following command sends the TERM signal to job number 1:

```
$ kill -TERM %1
```

Because TERM is the default signal for `kill`, you can also give this command as `kill %1`. Give the command `kill` `l` (lowercase "l") to display a list of signal names.

A program that is interrupted often leaves matters in an unpredictable state: Temporary files may be left behind (when they are normally removed), and permissions may be changed. A well-written application traps, or detects, signals and cleans up before exiting. Most carefully written applications trap the INT, QUIT, and TERM signals.
To terminate a program, first try INT (press CONTROL-C, if the job is in the foreground). Because an application can be written to ignore these signals, you may need to use the KILL signal, which cannot be trapped or ignored; it is a "sure kill." Refer to page 693 for more information on kill. See also the related utility killall (page 695).

**getopts: Parses Options**

The `getopts` builtin (not available in tcsh) parses command line arguments, thereby making it easier to write programs that follow the Linux argument conventions. The syntax for `getopts` is

```
getopts optstring varname [arg ...]
```

where `optstring` is a list of the valid option letters, `varname` is the variable that receives the options one at a time, and `arg` is the optional list of parameters to be processed. If `arg` is not present, `getopts` processes the command line arguments. If `optstring` starts with a colon (:), the script takes care of generating error messages; otherwise, `getopts` generates error messages.

The `getopts` builtin uses the `OPTIND` (option index) and `OPTARG` (option argument) variables to store option-related values. When a shell script starts, the value of `OPTIND` is 1. Each time `getopts` locates an argument, it increments `OPTIND` to the index of the next option to be processed. If the option takes an argument, `bash` assigns the value of the argument to `OPTARG`.

The `getopts` builtin checks the option list for options that are in `optstring`. Each time through the loop, `getopts` stores the option letter it finds in `varname`.

Suppose that you want to write a program that can take three options:

1. A `b` option indicates that the program should ignore whitespace at the start of input lines.
2. A `t` option followed by the name of a directory indicates that the program should use that directory for temporary files. Otherwise, it should use `/tmp`.
3. A `u` option indicates that the program should translate all its output to uppercase.

In addition, the program should ignore all other options and end option processing when it encounters two hyphens (`-`).

The problem is to write the portion of the program that determines which options the user has supplied. The following solution does not use `getopts`:

```
SKIPBLANKS=

TMPDIR=/tmp
```
CASE=lower

while [[ "$1" = -* ]] # [[ = ]] does pattern match
do
    case $1 in
        -b) SKIPBLANKS=TRUE ;;
        -t) if [ -d "$2" ]
            then
                TMPDIR=$2
                shift
            fi
        else
            echo "$0: -t takes a directory argument." >&2
            exit 1
        fi
        -u) CASE=upper ;;
        --) break ;; # Stop processing options
        *) echo "$0: Invalid option $1 ignored." >&2 ;;
    esac
    shift
done

This program fragment uses a loop to check and *shift* arguments while the argument is not `--`. As long as the argument is not two hyphens, the program continues to loop through a *case* statement that checks for possible options. The `*` *case* label breaks out of the *while* loop. The `*` *case* label recognizes any option; it appears as the last *case* label to catch any unknown options, displays an error message, and allows processing to continue. On each pass through the loop, the program does a *shift* to get to the next argument. If an option takes an argument, the program does an extra *shift* to get past that argument.

The following program fragment processes the same options, but uses *getopts*:

```
SKIPBLANKS=
TMPDIR=/tmp
CASE=lower
```
while getopt :bt:u arg
do
case $arg in
  b)        SKIPBLANKS=TRUE ;;
  t)        if [ -d "OPTARG" ]
            then
              TMPDIR=OPTARG
            else
              echo "$0: OPTARG is not a directory." >&2
              exit 1
            fi ;;
  u)        CASE=upper ;;
  :)        echo "$0: Must supply an argument to -$OPTARG." >&2
            exit 1 ;;
  \\?)       echo "Invalid option -$OPTARG ignored." >&2 ;;
esac
done

In this version of the code, the while structure evaluates the getopt builtin each time it comes to the top of the loop. The getopt builtin uses the OPTIND variable to keep track of the index of the argument it is to process the next time it is called. There is no need to call shift in this example.

In the getopt version of the script the case patterns do not start with a hyphen because the value of arg is just the option letter (getopt strips off the hyphen). Also, getopt recognizes \ as the end of the options, so you do not have to specify it explicitly as in the case statement in the first example.

Because you tell getopt which options are valid and which require arguments, it can detect errors in the command line and handle them in two ways. This example uses a leading colon in optstring to specify that you check for and handle errors in your code; when getopt finds an invalid option, it sets varname to ? and OPTARG to the option letter. When it finds an option that is missing an argument, getopt sets varname to : and OPTARG to the option lacking an argument.

The ? case pattern specifies the action to take when getopt detects an invalid option. The : case pattern
specifies the action to take when `getopts` detects a missing option argument. In both cases `getopts` does not write any error message; it leaves that task to you.

If you omit the leading colon from `optstring`, both an invalid option and a missing option argument cause `varname` to be assigned the string `. `. `OPTARG` is not set and `getopts` writes its own diagnostic message to standard error. Generally this method is less desirable because you have less control over what the user sees when an error is made.

Using `getopts` will not necessarily make your programs shorter. Its principal advantages are that it provides a uniform programming interface and it enforces standard option handling.

**A Partial List of Builtins**

Table 11-6 lists some of the `bash` builtins. See "Listing bash builtins" on page 133 for instructions on how to display complete lists of builtins.
Expressions

An expression is composed of constants, variables, and operators that can be processed to return a value. This section covers arithmetic, logical, and conditional expressions as well as operators. Table 11-8 on page 505 lists the bash operators.

### Conditional evaluation

- `? :` Ternary operator

### Assignment

- `=, *=, /=, %=, +=, -=, <<=, >>=, &=, ^=, |=`

- `, ` Comma

### Arithmetic Evaluation

The Bourne Again Shell can perform arithmetic assignments and evaluate many different types of arithmetic expressions, all using integers. The shell performs arithmetic assignments in a number of ways. One is with arguments to the `let` builtin:

```
$ let "VALUE=VALUE * 10  + NEW"
```

In the preceding example, the variables `VALUE` and `NEW` contain integer values. Within a `let` statement you do not need to use dollar signs (`$`) in front of variable names. Double quotation marks must enclose a single argument, or expression, that contains SPACES. Because most expressions contain SPACES and need to be quoted, `bash` accepts `(( expression ))` as a synonym for `let "expression "`, obviating the need for both quotation marks and dollar signs:

```
$ ((VALUE=VALUE * 10 + NEW))
```

You can use either form wherever a command is allowed and can remove the SPACES if you like. In the following example, the asterisk (`*`) does not need to be quoted because the shell does not perform pathname expansion on the right side of an assignment (page 280):

```
$ let VALUE=VALUE*10+NEW
```

Because each argument to `let` is evaluated as a separate expression, you can assign values to more than one variable on a single line:

```
$ let "COUNT = COUNT + 1" VALUE=VALUE*10 + NEW
```

You need to use commas to separate multiple assignments within a set of double parentheses:
tip: Arithmetic evaluation versus arithmetic expansion

Arithmetic evaluation differs from arithmetic expansion. As explained on page 327, arithmetic expansion uses the syntax `$( expression )`, evaluates `expression`, and replaces `$( expression )` with the result. You can use arithmetic expansion to display the value of an expression or to assign that value to a variable.

Arithmetic evaluation uses the let `expression` or `(( expression ))` syntax, evaluates `expression`, and returns a status code. You can use arithmetic evaluation to perform a logical comparison or an assignment.

Logical expressions

You can use the `(( expression ))` syntax for logical expressions, although that task is frequently left to `[ expression ]`. The next example expands the `age_check` script (page 327) to include logical arithmetic evaluation in addition to arithmetic expansion:

```
$ cat age2

#!/bin/bash

echo -n "How old are you? "

read age

if ((30 < age && age < 60)); then
    echo "Wow, in $((60-age)) years, you'll be 60!"
else
    echo "You are too young or too old to play."
fi
```

$ age2

How old are you? 25

You are too young or too old to play.

The test-statement for the if structure evaluates two logical comparisons joined by a Boolean AND and returns 0 (true) if they are both true or 1 (false) otherwise.
Logical Evaluation (Conditional Expressions)

The syntax of a conditional expression is

```plaintext
[[
  expression
]
]```

where `expression` is a Boolean (logical) expression. You must precede a variable name with a dollar sign (`$`) within `expression`. The result of executing this built-in, like the `test` built-in, is a return status. The `conditions` allowed within the brackets are almost a superset of those accepted by `test` (page 794). Where the `test` built-in uses `&` as a Boolean AND operator, `[[ expression ]]` uses `&&`. Similarly, where `test` uses `|` as a Boolean OR operator, `[[ expression ]]` uses `||`.

You can replace the line that tests `age` in the `age2` script (preceding) with the following conditional expression. You must surround the `[[` and `]]` tokens with whitespace or a command terminator, and place dollar signs before the variables:

```bash
if [[ 30 < $age && $age < 60 ]]; then
```

You can also use `test`'s relational operators `gt`, `ge`, `lt`, `le`, `eq`, and `ne`:

```bash
if [[ 30 -lt $age && $age -lt 60 ]]; then
```

String comparisons

The `test` builtin tests whether strings are equal or unequal. The `[[ expression ]]` syntax adds comparison tests for string operators. The `>` and `<` operators compare strings for order (for example, "aa" < "bbb"). The `=` operator tests for pattern match, not just equality: `[[ string = pattern ]]` is true if `string` matches `pattern`. This operator is not symmetrical; the `pattern` must appear on the right side of the equal sign. For example, `[[ artist = a* ]]` is true (= 0), whereas `[[ a* = artist ]]` is false (= 1):

```bash
$ [[ artist = a* ]]
$ echo $?
0
$ [[ a* = artist ]]
$ echo $?
1
```

The next example uses a command list that starts with a compound condition. The condition tests that the directory
The next example uses a command list that starts with a compound condition. The condition tests that the directory `bin` and the file `src/myscript.bash` exist. If this is true, `cp` copies `src/myscript.bash` to `bin/myscript`. If the copy succeeds, `chmod` makes `myscript` executable. If any of these steps fails, `echo` displays a message.

```bash
$ [[ -d bin && -f src/myscript.bash ]] && cp src/myscript.bash \
   bin/myscript && chmod +x bin/myscript || echo "Cannot make \
   executable version of myscript"
```

**String Pattern Matching**

The Bourne Again Shell provides string pattern-matching operators that can manipulate pathnames and other strings. These operators can delete from strings prefixes or suffixes that match patterns. The four operators are listed in Table 11-7.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>#</td>
<td>Removes minimal matching prefixes</td>
</tr>
<tr>
<td>##</td>
<td>Removes maximal matching prefixes</td>
</tr>
<tr>
<td>%</td>
<td>Removes minimal matching suffixes</td>
</tr>
<tr>
<td>%%</td>
<td>Removes maximal matching suffixes</td>
</tr>
</tbody>
</table>

The syntax for these operators is

```bash
${varname op pattern}
```

where `op` is one of the operators listed in Table 11-7 and `pattern` is a match pattern similar to that used for filename generation. These operators are commonly used to manipulate pathnames so as to extract or remove components or to change suffixes:

```bash
$ SOURCEFILE=/usr/local/src/prog.c

$ echo ${SOURCEFILE#/*/}
local/src/prog.c

$ echo ${SOURCEFILE##/*/}
prog.c

$ echo ${SOURCEFILE%/*}
/usr/local/src

$ echo ${SOURCEFILE%%/*}
```
$ echo ${SOURCEFILE%.c}
/usr/local/src/prog

$ CHOPFIRST=${SOURCEFILE#/*/}

$ echo $CHOPFIRST
local/src/prog.c

$ NEXT=${CHOPFIRST%%/*}

$ echo $NEXT
local

Here the string-length operator, ${#name}, is replaced by the number of characters in the value of name:

$ echo $SOURCEFILE
/usr/local/src/prog.c

$ echo ${#SOURCEFILE}
21

Operators

Arithmetic expansion and arithmetic evaluation use the same syntax, precedence, and associativity of expressions as the C language. Table 11-8 lists operators in order of decreasing precedence (priority of evaluation); each group of operators has equal precedence. Within an expression you can use parentheses to change the order of evaluation.

Pipe

The pipe token has higher precedence than operators. You can use pipes anywhere in a command that you can use simple commands. For example, the command line

$ cmd1 | cmd2 || cmd3 | cmd4 && cmd5 | cmd6

is interpreted as if you had typed

$ ((cmd1 | cmd2) || (cmd3 | cmd4)) && (cmd5 | cmd6)

**tip**: Do not rely on rules of precedence: use parentheses
Do not rely on the precedence rules when you use compound commands. Instead, use parentheses to explicitly state the order in which you want the shell to interpret the commands.

**Increment and decrement operators**

The postincrement, postdecrement, preincrement, and predecrement operators work with variables. The preoperators, which appear in front of the variable name as in `++COUNT` and `--VALUE`, first change the value of the variable (`++` adds 1; `--` subtracts 1) and then provide the result for use in the expression. The post- operators appear after the variable name as in `COUNT++` and `VALUE--`; they first provide the unchanged value of the variable for use in the expression and then change the value of the variable.

```bash
$ N=10
$ echo $N
10
$ echo $((--N+3))
12
$ echo $N
9
$ echo $((N++ - 3))
6
$ echo $N
10

Remainder

The remainder operator (`%`) gives the remainder when its first operand is divided by its second. For example, the expression `$((15%7))` has the value 1.

**Boolean**

The result of a Boolean operation is either 0 (`false`) or 1 (`true`).

The `&&` (AND) and `||` (OR) Boolean operators are called short-circuiting operators. If the result of using one of these operators can be decided by looking only at the left operand, the right operand is not evaluated. The `&&` operator causes the shell to test the exit status of the command preceding it. If the command succeeded, `bash` executes the next command; otherwise, it skips the remaining commands on the command line. You can use this construct to execute commands conditionally:
$ mkdir bkup && cp -r src bkup

This compound command creates the directory `bkup`. If `mkdir` succeeds, the contents of directory `src` is copied recursively to `bkup`.

The `||` separator also causes `bash` to test the exit status of the first command but has the opposite effect: The remaining command(s) are executed only if the first one failed (that is, exited with nonzero status):

$ mkdir bkup || echo "mkdir of bkup failed" >> /tmp/log

The exit status of a command list is the exit status of the last command in the list. You can group lists with parentheses. For example, you could combine the previous two examples as

$ (mkdir bkup && cp -r src bkup) || echo "mkdir failed" >> /tmp/log

In the absence of parentheses, `&&` and `||` have equal precedence and are grouped from left to right. The following examples use the `true` and `false` utilities. These utilities do nothing and return `true` (0) and `false` (1) exit statuses, respectively:

$ false; echo $?
1

The `$?` variable holds the exit status of the preceding command (page 479). The next two commands yield an exit status of 1 (`false`):

$ true || false && false
$ echo $?
1

$ (true || false) && false
$ echo $?
1

Similarly the next two commands yield an exit status of 0 (`true`):

$ false && false || true
$ echo $?  
0

$ (false && false) || true  
$ echo $?  
0

Because || and && have equal precedence, the parentheses in the two preceding pairs of examples do nothing to change the order of operations.

Because the expression on the right side of a short-circuiting operator may never get executed, you must be careful with assignment statements in that location. The following example demonstrates what can happen:

$ ((N=10,Z=0))  
$ echo $((N || ((Z+=1)) ))  
1
$ echo $Z  
0

Because the value of N is nonzero, the result of the || (OR) operation is 1 (true), no matter what the value of the right side is. As a consequence ((Z+=1)) is never evaluated and Z is not incremented.

Ternary

The ternary operator, ?:, decides which of two expressions should be evaluated, based on the value returned from a third expression:

expression1 ? expression2 : expression3

If expression1 produces a false (0) value, expression3 is evaluated; otherwise, expression2 is evaluated. The value of the entire expression is the value of expression2 or expression3, depending on which one is evaluated. If expression1 is true, expression3 is not evaluated. If expression1 is false expression2 is not evaluated:

$ ((N=10,Z=0,COUNT=1))  
$ ((T=N>COUNT?++Z:--Z))  
$ echo $T  
1
Assignment

The assignment operators, such as + =, are shorthand notations. For example, \( N + = 3 \) is the same as \((N = N + 3)\).

Other bases

The following commands use the syntax `base # n` to assign base 2 (binary) values. First \( v1 \) is assigned a value of 0101 (5 decimal) and \( v2 \) is assigned a value of 0110 (6 decimal). The `echo` utility verifies the decimal values.

```bash
$ ((v1=2#0101))
$ ((v2=2#0110))
$ echo "$v1 and $v2"
5 and 6
```

Next the bitwise AND operator (`&`) selects the bits that are on in both 5 (0101 binary) and 6 (0110 binary). The result is binary 0100, which is 4 decimal.

```bash
$ echo $((v1 & v2))
4
```

The Boolean AND operator (`&&`) produces a result of 1 if both of its operands are nonzero and a result of 0 otherwise. The bitwise inclusive OR operator (`|`) selects the bits that are on in either 0101 or 0110, resulting in 0111, which is 7 decimal. The Boolean OR operator (`||`) produces a result of 1 if either of its operands is nonzero and a result of 0 otherwise.

```bash
$ echo $((v1 && v2))
1
$ echo $((v1 | v2))
7
$ echo $((v1 || v2))
1
```
Next the bitwise exclusive OR operator (^) selects the bits that are on in either, but not both, of the operands 0101 and 0110, yielding 0011, which is 3 decimal. The Boolean NOT operator (!) produces a result of 1 if its operand is 0 and a result of 0 otherwise. Because the exclamation point in $(( ! v1 ))$ is enclosed within double parentheses, it does not need to be escaped to prevent the shell from interpreting the exclamation point as a history event. The comparison operators produce a result of 1 if the comparison is true and a result of 0 otherwise.

```
$ echo $(( v1 ^ v2 ))
3
$ echo $(( ! v1 ))
0
$ echo $(( v1 < v2 ))
1
$ echo $(( v1 > v2 ))
0
```
Shell Programs

The Bourne Again Shell has many features that make it a good programming language. The structures that bash provides are not a random assortment. Rather, they have been chosen to provide most of the structural features that are in other procedural languages, such as C or Pascal. A procedural language provides the ability to

- Declare, assign, and manipulate variables and constant data. The Bourne Again Shell provides string variables, together with powerful string operators, and integer variables, along with a complete set of arithmetic operators.
- Break large problems into small ones by creating subprograms. The Bourne Again Shell allows you to create functions and call scripts from other scripts. Shell functions can be called recursively; that is, a Bourne Again Shell function can call itself. You may not need to use recursion often, but it may allow you to solve some apparently difficult problems with ease.
- Execute statements conditionally, using statements such as if.
- Execute statements iteratively, using statements such as while and for.
- Transfer data to and from the program, communicating with both data files and users.

Programming languages implement these capabilities in different ways but with the same ideas in mind. When you want to solve a problem by writing a program, you must first figure out a procedure that leads you to a solution— that is, an algorithm. Typically you can implement the same algorithm in roughly the same way in different programming languages, using the same kinds of constructs in each language.

Chapter 8 and this chapter have introduced numerous bash features, many of which are useful for interactive use as well as for shell programming. This section develops two complete shell programs, demonstrating how to combine some of these features effectively. The programs are presented as problems for you to solve along with sample solutions.

A Recursive Shell Script

A recursive construct is one that is defined in terms of itself. Alternatively, you might say that a recursive program is one that can call itself. This may seem circular, but it need not be. To avoid circularity a recursive definition must have a special case that is not self-referential. Recursive ideas occur in everyday life. For example, you can define an ancestor as your mother, your father, or one of their ancestors. This definition is not circular; it specifies unambiguously who your ancestors are: your mother or your father, or your mother's mother or father or your father's mother or father, and so on.

A number of Linux system utilities can operate recursively. See the ᵃR option to the chmod (page 604), chown (page 608), and cp (page 616) utilities for examples.

Solve the following problem by using a recursive shell function:

Write a shell function named makepath that, given a pathname, creates all components in that pathname as directories. For example, the command makepath a/b/c/d should create directories a, a/b, a/b/c, and a/b/c/d. (The mkdir utility supports a ᵃp option that does exactly this. Solve the problem without using mkdir ᵃp.)

One algorithm for a recursive solution follows:

1. Examine the path argument. If it is a null string or if it names an existing directory, do nothing and return.
2. If it is a simple path component, create it (using `mkdir`) and return.

3. Otherwise, call `makepath` using the path prefix of the original argument. This step eventually creates all the directories up to the last component, which you can then create with `mkdir`.

In general, a recursive function must invoke itself with a simpler version of the problem than it was given until it is finally called with a simple case that does not need to call itself. Following is one possible solution based on this algorithm:

```bash
makepath

# this is a function
# enter it at the keyboard, do not run it as a shell script
#
function makepath()
{
    if [[ ${#1} -eq 0 || -d "$1" ]]
    then
        return 0        # Do nothing
    fi
    if [[ "${1%/*}" = "$1" ]]
    then
        mkdir $1
        return $?
    fi
    makepath ${1%/*} || return 1
    mkdir $1
    return $?
}
```

In the test for a simple component (the `if` statement in the middle of the function), the left expression is the argument after the shortest suffix that starts with a `/` character has been stripped away (page 504). If there is no such character (for example, if `$1` is `alex`), nothing is stripped off and the two sides are equal. If the argument is a simple filename
preceded by a slash, such as /usr, the expression $\{1%/^\ast\}$ evaluates to a null string. To make the function work in this case, you must take two precautions: Put the left expression within quotation marks and ensure that the recursive function behaves sensibly when it is passed a null string as an argument. In general, good programs are robust: They should be prepared for borderline, invalid, or meaningless input and behave appropriately in such cases.

By giving the following command from the shell you are working in, you turn on debugging tracing so that you can watch the recursion work:

```
$ set -o xtrace
```

(Give the same command, but replace the hyphen with a plus sign (+) to turn debugging off.) With debugging turned on, the shell displays each line in its expanded form as it executes the line. A + precedes each line of debugging output. In the following example, the first line that starts with + shows the shell calling `makepath`. The `makepath` function is called from the command line with arguments of `a/b/c`. Subsequently it calls itself with arguments of `a/b` and finally `a`. All the work is done (using `mkdir`) as each call to `makepath` returns.

```
$ makepath a/b/c
+ makepath a/b/c
+ [[ 5 -eq 0 ]]  
+ [[ -d a/b/c ]]  
+ [[ a/b = \a\b\c ]]  
+ makepath a/b
+ [[ 3 -eq 0 ]]  
+ [[ -d a/b ]]  
+ [[ a = \a\b ]]  
+ makepath a
+ [[ 1 -eq 0 ]]  
+ [[ -d a ]]  
+ [[ a = \a ]]  
+ mkdir a
+ return 0
+ mkdir a/b
+ return 0
```
The function works its way down the recursive path and back up again.

It is instructive to invoke `makepath` with an invalid path and see what happens. The following example, run with debugging turned on, tries to create the path `/a/b`, which requires that you create directory `a` in the root directory. Unless you have permission to write to the root directory, you are not permitted to create this directory.

```
$ makepath /a/b
+ makepath /a/b
+ [[ 4 -eq 0 ]]
+ [[ -d /a/b ]]
+ [[ /a = \\

+ makepath /a
+ [[ 2 -eq 0 ]]
+ [[ -d /a ]]
+ [[ '' = \\
+ makepath
+ [[ 0 -eq 0 ]]
+ return 0
+ mkdir /a
mkdir: cannot create directory '/a': Permission denied
```

The recursion stops when `makepath` is denied permission to create the `/a` directory. The error return is passed all the way back, so the original `makepath` exits with nonzero status.

**tip: Use local variables with recursive functions**

The preceding example glossed over a potential problem that you may encounter when you use a recursive function. During the execution of a recursive function, many separate instances of that function may be active simultaneously. All but one of them are waiting for their child invocation to complete.
Because functions run in the same environment as the shell that calls them, variables are implicitly shared by a shell and a function it calls so that all instances of the function share a single copy of each variable. Sharing variables can give rise to side effects that are rarely what you want. As a rule, you should use `typeset` to make all variables of a recursive function be local variables. See page 477 for more information.

The quiz Shell Script

Solve the following problem using a bash script:

Write a generic multiple-choice quiz program. The program should get its questions from data files, present them to the user, and keep track of the number of correct and incorrect answers. The user must be able to exit from the program at any time with a summary of results to that point.

The detailed design of this program and even the detailed description of the problem depend on a number of choices: How will the program know which subjects are available for quizzes? How will the user choose a subject? How will the program know when the quiz is over? Should the program present the same questions (for a given subject) in the same order each time, or should it scramble them?

Of course, you can make many perfectly good choices that implement the specification of the problem. The following details narrow the problem specification:

- Each subject will correspond to a subdirectory of a master quiz directory. This directory will be named in the environment variable `QUIZDIR`, whose default will be `/usr/games/quiz`. For example, you could have the following directories correspond to the subjects engineering, art, and politics: `/usr/games/quiz/engineering`, `/usr/games/quiz/art`, and `/usr/games/quiz/politics`.

- Each subject can have several questions. Each question is represented by a file in its subject's directory.

- The first line of each file that represents a question is the text of the question. If it takes more than one line, you must escape the `NEWLINE` with a backslash. (This setup makes it easy to read a single question with the `read` builtin.) The second line of the file is an integer that specifies the number of choices. The next lines are the choices themselves. The last line is the correct answer. Following is a sample question file:

  **Who discovered the principle of the lever?**

    4

    Euclid

    Archimedes

    Thomas Edison

    The Lever Brothers

    Archimedes

- The program presents all the questions in a subject directory. At any point the user can interrupt the quiz with `CONTROL-C`, whereupon the program will summarize the results so far and exit. If the user does not
interrupt, the program summarizes the results and exits when it has asked all questions for the chosen subject.

• The program scrambles the questions in a subject before presenting them.

Following is a top-level design for this program:
1. Initialize. This involves a number of steps, such as setting the counts of the number of questions asked so far and the number of correct and wrong answers to zero. Sets up to trap CONTROL-C.

2. Present the user with a choice of subjects and get the user's response.

3. Change to the corresponding subject directory.

4. Determine the questions to be asked (that is, the filenames in that directory). Arrange them in random order.

5. Repeatedly present questions and ask for answers until the quiz is over or is interrupted by the user.

6. Present the results and exit.

Clearly some of these steps (such as step 3) are simple, whereas others (such as step 4) are complex and worthy of analysis on their own. Use shell functions for any complex step, and use the trap builtin to handle a user interrupt.

Here is a skeleton version of the program with empty shell functions:

```sh
function initialize
{
  # Initializes variables.
}

function choose_subj
{
  # Writes choice to standard output.
}

function scramble
```

# Stores names of question files, scrambled, 
# in an array variable named questions.
{
  function ask
  {
    # Reads a question file, asks the question, and checks the 
    # answer. Returns 1 if the answer was correct, 0 otherwise. If it 
    # encounters an invalid question file, exit with status 2.
  }

  function summarize
  {
    # Presents the user's score.
  }

  # Main program
  initialize                        # Step 1 in top-level design

  subject=$(choose_subj)            # Step 2
  [[ $? -eq 0 ]] || exit 2          # If no valid choice, exit

  cd $subject || exit 2             # Step 3
  echo                              # Skip a line
  scramble                          # Step 4
for ques in ${questions[*]}; do   # Step 5
   ask $ques
   result=$?
   (( num_ques=num_ques+1 ))
   if [[ $result == 1 ]]; then
      (( num_correct += 1 ))
   fi
   echo                          # Skip a line between questions
   sleep ${QUIZDELAY:=1}
done

summarize                         # Step 6
exit 0

To make reading the results a bit easier for the user, a sleep call appears inside the question loop. It delays $QUIZDELAY seconds (default = 1) between questions.

Now the task is to fill in the missing pieces of the program. In a sense this program is being written backward. The details (the shell functions) come first in the file but come last in the development process. This common programming practice is called top-down design. In top-down design you fill in the broad outline of the program first and supply the details later. In this way you break the problem up into smaller problems, each of which you can work on independently. Shell functions are a great help in using the top-down approach.

One way to write the initialize function follows. The cd command causes QUIZDIR to be the working directory for the rest of the script and defaults to /usr/games/quiz if QUIZDIR is not set.

    function initialize ()
    {
    trap 'summarize ; exit 0' INT          # Handle user interrupts
    num_ques=0                            # Number of questions asked so far
    num_correct=0                         # Number answered correctly so far
    first_time=true                       # true until first question is asked
    cd ${QUIZDIR:=/usr/games/quiz} || exit 2
Be prepared for the `cd` command to fail. The directory may be unsearchable or conceivably another user may have removed it. The preceding function exits with a status code of 2 if `cd` fails.

The next function, `choose_subj`, is a bit more complicated. It displays a menu using a `select` statement:

```bash
function choose_subj () {
subjects=($(ls))
PS3="Choose a subject for the quiz from the preceding list: "
select Subject in ${subjects[*]}; do
  if [[ -z "$Subject" ]]; then
    echo "No subject chosen. Bye." >&2
    exit 1
  fi
  echo $Subject
  return 0
done
}
```

The function first uses an `ls` command and command substitution to put a list of subject directories in the `subjects` array. Next the `select` structure (page 466) presents the user with a list of subjects (the directories found by `ls`) and assigns the chosen directory name to the `Subject` variable. Finally the function writes the name of the subject directory to standard output. The main program uses command substitution to assign this value to the `subject` variable.

The `scramble` function presents a number of difficulties. In this solution it uses an array variable (`questions`) to hold the names of the questions. It scrambles the entries in an array using the `RANDOM` variable (each time you reference `RANDOM` it has the value of a [random] integer between 0 and 32767):

```bash
function scramble () {
  typeset -i index quescount
  questions=($(ls))
```
quescount=${#questions[*]}                # Number of elements
((index=quescount-1))

while [[ $index > 0 ]]; do
    ((target=RANDOM % index))
    exchange $target $index
    ((index -= 1))
done

This function initializes the array variable questions to the list of filenames (questions) in the working directory. The variable quescount is set to the number of such files. Then the following algorithm is used: Let the variable index count down from quescount - 1 (the index of the last entry in the array variable). For each value of index, the function chooses a random value target between 0 and index, inclusive. The command

((target=RANDOM % index))

produces a random value between 0 and index - 1 by taking the remainder (the % operator) when $RANDOM is divided by index. The function then exchanges the elements of questions at positions target and index. It is convenient to do this in another function named exchange:

function exchange ()
{
    temp_value=${questions[$1]}
    questions[$1]=${questions[$2]}
    questions[$2]=$temp_value
}

The ask function also uses the select structure. It reads the question file named in its argument and uses the contents of that file to present the question, accept the answer, and determine whether the answer is correct. (See the code that follows.)

The ask function uses file descriptor 3 to read successive lines from the question file, whose name was passed as an argument and is represented by $1 in the function. It reads the question into the ques variable and the number of questions into num_opts. The function constructs the variable choices by initializing it to a null string and successively appending the next choice. Then it sets PS3 to the value of ques and uses a select structure to prompt the user with ques. The select structure places the user's answer in answer, and the function then checks it against
the correct answer from the file.

The construction of the \texttt{choices} variable is done with an eye toward avoiding a potential problem. Suppose that one answer has some whitespace in it. Then it might appear as two or more arguments in \texttt{choices}. To avoid this problem, make sure that \texttt{choices} is an array variable. The \texttt{select} statement does the rest of the work:

\begin{verbatim}

$ cat quiz
#!/bin/bash

# remove the # on the following line to turn on debugging
# set -o xtrace

#initialize

function initialize ()
{
  trap 'summarize ; exit 0' INT  # Handle user interrupts
  num_ques=0                   # Number of questions asked so far
  num_correct=0                # Number answered correctly so far
  first_time=true              # true until first question is asked
  cd ${QUIZDIR:=/usr/games/quiz} || exit 2
}

#function choose_subj ()
{
  subjects=($(ls))
  PS3="Choose a subject for the quiz from the preceding list: "
  select Subject in ${subjects[*]}; do

\end{verbatim}
if [[ -z "$Subject" ]]; then
    echo "No subject chosen. Bye." >&2
    exit 1
fi

echo $Subject
return 0
done
}

#==================
function exchange () {
    
    temp_value=${questions[$1]}
    questions[$1]=${questions[$2]}
    questions[$2]=$temp_value
}

#==================
function scramble () {
    
    typeset -i index quescount
    questions=($(ls))
    quescount=${#questions[*]}  # Number of elements
    
    while [[ $index > 0 ]]; do
        (target=RANDOM % index)
        exchange $target $index
((index -= 1))
done
}

#==================

function ask ()
{
exec 3<$1
read -u3 ques || exit 2
read -u3 num_opts || exit 2

index=0
choices=()

while (( index < num_opts )); do
    read -u3 next_choice || exit 2
    choices="${choices[@]} "$next_choice"
((index += 1))
done

read -u3 correct_answer || exit 2
exec 3<&-

if [[ $first_time = true ]]; then
    first_time=false
    echo -e "You may press the interrupt key at any time to quit.\n"
fi

PS3="$ques" " # Make $ques the prompt for select
select answer in "${choices[@]}"; do
    if [[ -z "$answer" ]]; then
        echo "Not a valid choice. Please choose again."
    elif [[ "$answer" = "$correct_answer" ]]; then
        echo "Correct!"
        return 1
    else
        echo "No, the answer is $correct_answer."
        return 0
    fi
done

#==================
function summarize () {

    # Skip a line
    echo

    if (( num_ques == 0 )); then
        echo "You did not answer any questions"
        exit 0
    fi

    (( percent=num_correct*100/num_ques ))
    echo "You answered $num_correct questions correctly, out of $num_ques total questions."
    echo "Your score is $percent percent."
}

Chapter Summary

The shell is a programming language. Programs written in this language are called shell scripts, or simply scripts. Shell scripts provide the decision and looping control structures present in high-level programming languages while allowing easy access to system utilities and user programs. Shell scripts can use functions to modularize and simplify complex tasks.

Control structures

The control structures that use decisions to select alternatives are if...then, if...then...else, and if...then...elif. The case control structure provides a multiway branch and can be used when you want to express alternatives using a simple pattern-matching syntax.

The looping control structures are for...in, for, until, and while. These structures perform one or more tasks repetitively.

The break and continue control structures alter control within loops: break transfers control out of a loop, and continue transfers control immediately to the top of a loop.

The Here document allows input to a command in a shell script to come from within the script itself.

File descriptors

The Bourne Again Shell provides the ability to manipulate file descriptors. Coupled with the read and echo builtins, file descriptors allow shell scripts to have as much control over input and output as programs written in lower-level languages.

Variables

You assign attributes, such as readonly, to bash variables using the typeset builtin. The Bourne Again Shell provides operators to perform pattern matching on variables, provide default values for variables, and evaluate the length of variables. This shell also supports array variables and local variables for functions and provides built-in integer arithmetic capability, using the let builtin and an expression syntax similar to the C programming language.

Builtins

Bourne Again Shell builtins include type, read, exec, TRap, kill, and getopts. The type builtin displays information about a command, including its location; read allows a script to accept user input.

The exec builtin executes a command without creating a new process. The new command overlays the current process, assuming the same environment and PID number of that process. This builtin executes user programs and other Linux commands when it is not necessary to return control to the calling process.

The TRap builtin catches a signal sent by Linux to the process running the script and allows you to specify actions to be taken upon receipt of one or more signals. You can use this builtin to cause a script to ignore the signal that is sent when the user presses the interrupt key.

The kill builtin allows you to terminate a running program. The getopts builtin parses command line arguments, making it easier to write programs that follow standard Linux conventions for command line arguments.
and options.

Utilities in scripts

In addition to using control structures, builtins, and functions, shell scripts generally call Linux utilities. The find utility, for instance, is commonplace in shell scripts that search for files in the system hierarchy and can perform a vast range of tasks, from simple to complex.

A well-written shell script adheres to standard programming practices, such as specifying the shell to execute the script on the first line of the script, verifying the number and type of arguments that the script is called with, displaying a standard usage message to report command line errors, and redirecting all informational messages to standard error.

Expressions

There are two basic types of expressions: arithmetic and logical. Arithmetic expressions allow you to do arithmetic on constants and variables, yielding a numeric result. Logical (Boolean) expressions compare expressions or strings, or test conditions to yield a true or false result. As with all decisions within Linux shell scripts, a true status is represented by the value zero; false, by any nonzero value.
1. Rewrite the journal script of Chapter 8 (question 5, page 335) by adding commands to verify that the user has write permission for a file named journal-file in the user's home directory, if such a file exists. The script should take appropriate actions if journal-file exists and the user does not have write permission to the file. Verify that the modified script works.

2. The special parameter "$@" is referenced twice in the out script (page 442). Explain what would be different if the parameter "$*" were used in its place.

3. Write a filter that takes a list of files as input and outputs the basename (page 465) of each file in the list.

4. a. Write a function that takes a single filename as an argument and adds execute permission to the file for the user.

   b. When might such a function be useful?

   c. Revise the script so that it takes one or more filenames as arguments and adds execute permission for the user for each file argument.

   d. What can you do to make the function available every time you log in?

   e. Suppose that, in addition to having the function available on subsequent login sessions, you want to make the function available now in your current shell. How would you do so?

5. When might it be necessary or advisable to write a shell script instead of a shell function? Give as many reasons as you can think of.

6. Write a shell script that displays the names of all directory files, but no other types of files, in the working directory.

7. Write a script to display the time every 15 seconds. Read the date man page and display the time, using the %r field descriptor. Clear the window (using the clear command) each time before you display the time.

8. Enter the following script named savefiles, and give yourself execute permission to the file:

```bash
$ cat savefiles
#! /bin/bash

echo "Saving files in current directory in file savethem."

exec > savethem

for i in *
```
do
  echo
  "==================================================="
  echo "File: $i"
  echo
  "==================================================="
  cat "$i"
done

a. What error message do you get when you execute this script? Rewrite the script so that the error does not occur, making sure the output still goes to savethem.

b. What might be a problem with running this script twice in the same directory? Discuss a solution to this problem.

9. Read the bash man or info page, try some experiments, and answer the following questions:
   a. How do you export a function?
   b. What does the hash builtin do?
   c. What happens if the argument to exec is not executable?

10. Using the find utility, perform the following tasks:
    a. List all files in the working directory and all subdirectories that have been modified within the last day.
    b. List all files that you have read access to on the system that are larger than 1 megabyte.
    c. Remove all files named core from the directory structure rooted at your home directory.
    d. List the inode numbers of all files in the working directory whose filenames end in .c.
    e. List all files that you have read access to on the root filesystem that have been modified in the last 30 days.

11. Write a short script that tells you whether the permissions for two files, whose names are given as arguments to the script, are identical. If the permissions for the two files are identical, output the common permission field. Otherwise, output each filename followed by its permission
field. (*Hint:* Try using the `cut` utility.)

12. Write a script that takes the name of a directory as an argument and searches the file hierarchy rooted at that directory for zero-length files. Write the names of all zero-length files to standard output. If there is no option on the command line, have the script delete the file after displaying its name, asking the user for confirmation, and receiving positive confirmation. A `f` (force) option on the command line indicates that the script should display the filename but not ask for confirmation before deleting the file.
Advanced Exercises

13. Write a script that takes a colon-separated list of items and outputs the items, one per line, to standard output (without the colons).

14. Generalize the script written in exercise 13 so that the character separating the list items is given as an argument to the function. If this argument is absent, the separator should default to a colon.

15. Write a function named `funload` that takes as its single argument the name of a file containing other functions. The purpose of `funload` is to make all functions in the named file available in the current shell; that is, `funload` loads the functions from the named file. To locate the file, `funload` searches the colon-separated list of directories given by the environment variable `FUNPATH`. Assume that the format of `FUNPATH` is the same as `PATH` and that searching `FUNPATH` is similar to the shell’s search of the `PATH` variable.

16. Rewrite `bundle` (page 469) so that the script it creates takes an optional list of filenames as arguments. If one or more filenames are given on the command line, only those files should be re-created; otherwise, all files in the shell archive should be re-created. For example, suppose that all files with the filename extension `.c` are bundled into an archive named `srcshell`, and you want to unbundle just the files `test1.c` and `test2.c`. The following command will unbundle just these two files:

   ```bash
   $ bash srcshell test1.c test2.c
   ```

17. What kind of links will the `lnks` script (page 445) not find? Why?

18. In principle, recursion is never necessary. It can always be replaced by an iterative construct, such as `while` or `until`. Rewrite `makepath` (page 511) as a nonrecursive function. Which version do you prefer? Why?

19. Lists are commonly stored in environment variables by putting a colon (:) between each of the list elements. (The value of the `PATH` variable is a good example.) You can add an element to such a list by catenating the new element to the front of the list, as in

   ```bash
   PATH=/opt/bin:$PATH
   ```

   If the element you add is already in the list, you now have two copies of it in the list. Write a shell function named `addenv` that takes two arguments: (1) the name of a shell variable and (2) a string to prepend to the list that is the value of the shell variable only if that string is not already an element of the list. For example, the call
addenv PATH /opt/bin

would add /opt/bin to PATH only if that pathname is not already in PATH. Be sure that your
solution works even if the shell variable starts out empty. Also make sure that you check the list
elements carefully. If /usr/opt/bin is in PATH but /opt/bin is not, the example just given
should still add /opt/bin to PATH. (Hint: You may find this exercise easier to complete if you
first write a function locate_field that tells you whether a string is an element in the value of a
variable.)

20. Write a function that takes a directory name as an argument and writes to standard output the
maximum of the lengths of all filenames in that directory. If the function's argument is not a
directory name, write an error message to standard output and exit with nonzero status.

21. Modify the function you wrote for exercise 20 to descend all subdirectories of the named
directory recursively and to find the maximum length of any filename in that hierarchy.

22. Write a function that lists the number of regular files, directories, block special files, character
special files, FIFOs, and symbolic links in the working directory. Do this in two different ways:

a. Use the first letter of the output of Is [-I] to determine a file's type.

b. Use the file type condition tests of the [[ expression ]] syntax to determine a file's
type.

23. Modify the quiz program (page 518) so that the choices for a question are randomly arranged.
Chapter 12. The gawk Pattern Processing Language

gawk: Controlling Input 554
Coprocess: Two-Way I/O 557
Getting Input from a Network 558

Error Messages 559

The gawk (GNU awk) utility is a pattern-scanning and processing language that searches one or more files to see whether they contain records (usually lines) that match specified patterns. It processes lines by performing actions, such as writing the record to standard output or incrementing a counter, each time it finds a match. As opposed to procedural languages, the gawk language is data driven: You describe the data you want to work with and tell gawk what to do with the data once it finds it.

You can use gawk to generate reports or filter text. It works equally well with numbers and text; when you mix the two, gawk usually comes up with the right answer. The authors of awk (Alfred V. Aho, Peter J. Weinberger, and Brian W. Kernighan), on which gawk is based, designed the original utility to be easy to use. To achieve this end they sacrificed execution speed.

The gawk utility takes many of its constructs from the C programming language. It includes the following features:

- Flexible format
- Conditional execution
- Looping statements
- Numeric variables
• String variables
• Regular expressions
• Relational expressions
• C's `printf`
• Coprocess execution
• Network data exchange
**Syntax**

A `gawk` command line has the following syntax:

```
gawk [ options ] [ program ] [ file-list ]
```

```
gawk [ options ] -f program-file [ file-list ]
```

The `gawk` utility takes its input from files you specify on the command line or from standard input. An advanced command, `getline`, gives you more choices about where input comes from and how you read it. Using a coprocess, `gawk` can interact with another program or exchange data over a network. Unless you redirect output from `gawk`, it goes to standard output.
Arguments

In the preceding syntax, *program* is a *gawk* program that you include on the command line. The *program-file* is the name of the file that holds a *gawk* program. Putting the program on the command line allows you to write short *gawk* programs without having to create a separate *program-file*. To prevent the shell from interpreting the *gawk* commands as shell commands, enclose the *program* within single quotation marks. Putting a long or complex program in a file can reduce errors and retyping.

The *file-list* contains pathnames of the ordinary files that *gawk* processes. These files are the input files. When you do not specify a *file-list*, *gawk* takes input from standard input or as specified by *getline* (page 554) or a coprocess (page 557).
Options

- **field-separator fs**
  
  Uses *fs* as the value of the input field separator (*FS* variable).

- **file program-file**
  
  If *program-file*
  
  Reads the *gawk* program from the file named *program-file* instead of the command line. You can specify this option more than once on a command line.

- **help**
  
  Summarizes how to use *gawk*.

- **lint**
  
  Warns about constructs that may not be correct or portable.

- **posix**
  
  Runs a POSIX-compliant version of *gawk*. This option introduces some restrictions; see the *gawk* man page for details.

- **traditional**
  
  Ignores the new GNU features in a *gawk* program, making the program conform to UNIX *awk*.

- **assign var =value**
  
  Assigns *value* to the variable *var*. The assignment takes place prior to execution of the *gawk* program and is available within the *BEGIN* pattern (page 531). You can specify this option more than once on a command line.
Notes

The gawk utility is the GNU version of UNIX awk. For convenience many Linux systems provide a link from /bin/awk to /bin/gawk so that you can run the program using either name.

See page 554 for advanced gawk commands and page 559 for examples of gawk error messages.
Language Basics

A **gawk program** (from the command line or from **program-file**) consists of one or more lines containing a **pattern** and/or **action** in the following format:

```
  pattern {  action  }
```

The **pattern** selects lines from the input. The **gawk** utility performs the **action** on all lines that the **pattern** selects. The braces surrounding the **action** enable **gawk** to differentiate it from the **pattern**. If a **program** line does not contain a **pattern**, **gawk** selects all lines in the input. If a **program** line does not contain an **action**, **gawk** copies the selected lines to standard output.

To start, **gawk** compares the first line of input (from the **file-list** or standard input) with each **pattern** in the **program**. If a **pattern** selects the line (if there is a match), **gawk** takes the **action** associated with the **pattern**. If the line is not selected, **gawk** takes no **action**. When **gawk** has completed its comparisons for the first line of input, it repeats the process for the next line of input, continuing this process of comparing subsequent lines of input until it has read all of the input.

If several **patterns** select the same line, **gawk** takes the **actions** associated with each of the **patterns** in the order in which they appear in the **program**. It is possible for **gawk** to send a single line from the input to standard output more than once.

Patterns

You can use a regular expression (**Appendix A**), enclosed within slashes, as a **pattern**. The ~ operator tests whether a field or variable matches a regular expression. The !~ operator tests for no match. You can perform both numeric and string comparisons using the relational operators listed in **Table 12-1**. You can combine any of the **patterns** using the Boolean operators || (OR) or && (AND).

**Table 12-1. Relational operators**

<table>
<thead>
<tr>
<th>Relop</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;</td>
<td>Less than</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Less than or equal to</td>
</tr>
<tr>
<td>=</td>
<td>Equal to</td>
</tr>
<tr>
<td>!=</td>
<td>Not equal to</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Greater than or equal to</td>
</tr>
<tr>
<td>&gt;</td>
<td>Greater than</td>
</tr>
</tbody>
</table>

BEGIN and END

Two unique **patterns**, **BEGIN** and **END**, execute commands before **gawk** starts its processing and after it finishes. The **gawk** utility executes the **actions** associated with the **BEGIN pattern** before, and with the **END pattern** after, it processes all the input.

, (comma)
The comma is the range operator. If you separate two patterns with a comma on a single gawk program line, gawk selects a range of lines, beginning with the first line that matches the first pattern. The last line gawk selects is the next subsequent line that matches the second pattern. If no line matches the second pattern, gawk selects every line through the end of the input. After gawk finds the second pattern, it begins the process again by looking for the first pattern again.

**Actions**

The action portion of a gawk command causes gawk to take that action when it matches a pattern. When you do not specify an action, gawk performs the default action, which is the print command (explicitly represented as {print}). This action copies the record (normally a line) from the input to standard output.

When you follow a print command with arguments, gawk displays only the arguments you specify. These arguments can be variables or string constants. You can send the output from a print command to a file (>), append it to a file (>>), or send it through a pipe to the input of another program ( | ). A coprocess (|&) is a two-way pipe that exchanges data with a program running in the background (page 557).

Unless you separate items in a print command with commas, gawk catenates them. Commas cause gawk to separate the items with the output field separator (OFS, normally a SPACE).

You can include several actions on one line by separating them with semicolons.

**Comments**

The gawk utility disregards anything on a program line following a pound sign (#). You can document a gawk program by preceding comments with this symbol.

**Variables**

Although you do not need to declare gawk variables prior to their use, you can optionally assign initial values to them. Unassigned numeric variables are initialized to 0; string variables are initialized to the null string. In addition to user variables, gawk maintains program variables. You can use both user and program variables in the pattern and in the action portion of a gawk program. Table 12-2 lists a few program variables.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>$0</td>
<td>The current record (as a single variable)</td>
</tr>
<tr>
<td>$1-$n</td>
<td>Fields in the current record</td>
</tr>
<tr>
<td>FILENAME</td>
<td>Name of the current input file (null for standard input)</td>
</tr>
<tr>
<td>FS</td>
<td>Input field separator (default: SPACE or TAB)</td>
</tr>
<tr>
<td>NF</td>
<td>Number of fields in the current record</td>
</tr>
<tr>
<td>NR</td>
<td>Record number of the current record</td>
</tr>
<tr>
<td>OFS</td>
<td>Output field separator (default: SPACE)</td>
</tr>
<tr>
<td>ORS</td>
<td>Output record separator (default: NEWLINE)</td>
</tr>
<tr>
<td>RS</td>
<td>Input record separator (default: NEWLINE)</td>
</tr>
</tbody>
</table>

In addition to initializing variables within a program, you can use the assign (iv) option to initialize variables on
In addition to initializing variables within a program, you can use the `assign` option on the command line. This feature is useful when the value of a variable changes from one run of `gawk` to the next.

By default the input and output record separators are NEWLINE characters. Thus `gawk` takes each line of input to be a separate record and appends a NEWLINE to the end of each output record. By default the input field separators are SPACEs and TABs. The default output field separator is a SPACE. You can change the value of any of the separators at any time by assigning a new value to its associated variable either from within the program or from the command line by using the `assign (v)` option.

**Functions**

Table 12-3 lists a few of the functions that `gawk` provides for manipulating numbers and strings.

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>length(str)</code></td>
<td>Returns the number of characters in <code>str</code>; without an argument, returns the number of characters in the current record</td>
</tr>
<tr>
<td><code>int(num)</code></td>
<td>Returns the integer portion of <code>num</code></td>
</tr>
<tr>
<td><code>index(str1,str2)</code></td>
<td>Returns the index of <code>str2</code> in <code>str1</code> or 0 if <code>str2</code> is not present</td>
</tr>
<tr>
<td><code>split(str,arr,del)</code></td>
<td>Places elements of <code>str</code>, delimited by <code>del</code>, in the array <code>arr [1]...arr [n]</code>; returns the number of elements in the array</td>
</tr>
<tr>
<td><code>sprintf(fmt,args)</code></td>
<td>Formats <code>args</code> according to <code>fmt</code> and returns the formatted string; mimics the C programming language function of the same name</td>
</tr>
<tr>
<td><code>substr(str,pos,len)</code></td>
<td>Returns the substring of <code>str</code> that begins at <code>pos</code> and is <code>len</code> characters long</td>
</tr>
<tr>
<td><code>tolower(str)</code></td>
<td>Returns a copy of <code>str</code> in which all uppercase letters are replaced with their lowercase counterparts</td>
</tr>
<tr>
<td><code>toupper(str)</code></td>
<td>Returns a copy of <code>str</code> in which all lowercase letters are replaced with their uppercase counterparts</td>
</tr>
</tbody>
</table>

**Arithmetic Operators**

The `gawk` arithmetic operators listed in Table 12-4 are from the C programming language.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>*</code></td>
<td>Multiplies the expression preceding the operator by the expression following it</td>
</tr>
<tr>
<td><code>/</code></td>
<td>Divides the expression preceding the operator by the expression following it</td>
</tr>
<tr>
<td><code>%</code></td>
<td>Takes the remainder after dividing the expression preceding the operator by the expression following it</td>
</tr>
<tr>
<td><code>+</code></td>
<td>Adds the expression preceding the operator to the expression following it</td>
</tr>
<tr>
<td><code>-</code></td>
<td>Subtracts the expression following the operator from the expression preceding it</td>
</tr>
<tr>
<td><code>=</code></td>
<td>Assigns the value of the expression following the operator to the variable preceding it</td>
</tr>
<tr>
<td><code>++</code></td>
<td>Increments the variable preceding the operator</td>
</tr>
<tr>
<td><code>--</code></td>
<td>Decrements the variable preceding the operator</td>
</tr>
<tr>
<td><code>+=</code></td>
<td>Adds the expression following the operator to the variable preceding it and assigns the result to the variable preceding the operator</td>
</tr>
</tbody>
</table>
### Operator

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>−=</td>
<td>Subtracts the expression following the operator from the variable preceding it and assigns the result to the variable preceding the operator</td>
</tr>
<tr>
<td>*=</td>
<td>Multiplies the variable preceding the operator by the expression following it and assigns the result to the variable preceding the operator</td>
</tr>
<tr>
<td>/=</td>
<td>Divides the variable preceding the operator by the expression following it and assigns the result to the variable preceding the operator</td>
</tr>
<tr>
<td>%=</td>
<td>Assigns the remainder, after dividing the variable preceding the operator by the expression following it, to the variable preceding the operator</td>
</tr>
</tbody>
</table>

#### Associative Arrays

An associative array is one of `gawk`'s most powerful features. These arrays use strings as indexes. Using an associative array, you can mimic a traditional array by using numeric strings as indexes.

You assign a value to an element of an associative array just as you would assign a value to any other `gawk` variable. The syntax is

```
array[string] = value
```

where `array` is the name of the array, `string` is the index of the element of the array you are assigning a value to, and `value` is the value you are assigning to that element.

You can use a special `for` structure with an associative array. The syntax is

```
for (elem in array) action
```

where `elem` is a variable that takes on the value of each element of the array as the `for` structure loops through them, `array` is the name of the array, and `action` is the action that `gawk` takes for each element in the array. You can use the `elem` variable in this `action`.

The "Examples" section found later in this chapter contains programs that use associative arrays.

#### printf

You can use the `printf` command in place of `print` to control the format of the output that `gawk` generates. The `gawk` version of `printf` is similar to that found in the C language. A `printf` command has the following syntax:

```
printf("control-string", arg1, arg2, ..., argn)
```
The control-string determines how printf formats arg1, arg2, ..., argn. These arguments can be variables or other expressions. Within the control-string you can use \n to indicate a NEWLINE and \t to indicate a TAB. The control-string contains conversion specifications, one for each argument. A conversion specification has the following syntax:

```
%[
[ x 
[ . 
 y ]]
 conv
```

where \ causes printf to left-justify the argument; \ is the minimum field width, and .\ is the number of places to the right of a decimal point in a number. The conv indicates the type of numeric conversion and can be selected from the letters in Table 12-5. Refer to "Examples" later in this chapter for examples of how to use printf.

### Table 12-5. Numeric conversion

<table>
<thead>
<tr>
<th>conv</th>
<th>Type of conversion</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Decimal</td>
</tr>
<tr>
<td>e</td>
<td>Exponential notation</td>
</tr>
<tr>
<td>f</td>
<td>Floating-point number</td>
</tr>
<tr>
<td>g</td>
<td>Use f or e, whichever is shorter</td>
</tr>
<tr>
<td>o</td>
<td>Unsigned octal</td>
</tr>
<tr>
<td>s</td>
<td>String of characters</td>
</tr>
<tr>
<td>x</td>
<td>Unsigned hexadecimal</td>
</tr>
</tbody>
</table>

### Control Structures

Control (flow) statements alter the order of execution of commands within a gawk program. This section details the if...else, while, and for control structures. In addition, the break and continue statements work in conjunction with the control structures to alter the order of execution of commands. See page 436 for more information on control structures. You do not need to use braces around commands when you specify a single, simple command.

#### if...else

The if...else control structure tests the status returned by the condition and transfers control based on this status. The syntax of an if...else structure is shown below. The else part is optional.

```
if ( condition )
{
 commands
}
[else
```
The simple `if` statement shown here does not use braces:

```plaintext
if ($5 <= 5000) print $0
```

Next is a `gawk` program that uses a simple `if...else` structure. Again, there are no braces.

```plaintext
$ cat if1
BEGIN { 
    nam="sam"
    if (nam == "max")
        print "nam is max"
    else
        print "nam is not max, it is", nam
}
$ gawk -f if1
nam is not max, it is sam
```

`while`

The `while` structure loops through and executes the `commands` as long as the `condition` is true. The syntax of a `while` structure is

```plaintext
while
(
    condition
)
{
    commands
}
```

The next `gawk` program uses a simple `while` structure to display powers of 2. This example uses braces because the `while` loop contains more than one statement.
$ cat while1

BEGIN    {
    n = 1
    while (n <= 5)
        {
            print n "^2", 2**n
            n++
        }
    }

$ gawk -f while1

1^2 2
2^2 4
3^2 8
4^2 16
5^2 32

for

The syntax of a for control structure is

```
for
    (init; condition; increment)

{commands}
```

A for structure starts by executing the init statement, which usually sets a counter to 0 or 1. It then loops through the commands as long as the condition is true. After each loop it executes the increment statement. The for gawk program does the same thing as the preceding while program except that it uses a for statement, which makes the program simpler:
The `gawk` utility supports an alternative `for` syntax for working with associative arrays:

```
for (var in array)
{
   commands
}
```

This `for` structure loops through elements of the associative array named `array`, assigning the value of the index of each element of `array` to `var` each time through the loop.

```
END     {for (name in manuf) print name, manuf[name]}
```

`break`

The `break` statement transfers control out of a `for` or `while` loop, terminating execution of the innermost loop it appears in.

`continue`

The `continue` statement transfers control to the end of a `for` or `while` loop, causing execution of the innermost loop it appears in to continue with the next iteration.
Examples

cars data file

Many of the examples in this section work with the cars data file. From left to right the columns in the file contain each car's make, model, year of manufacture, mileage in thousands of miles, and price. All whitespace in this file is composed of single TABs (the file does not contain any SPACES).

$ cat cars
plym  fury  1970  73   2500
chevy malibu 1999  60  3000
ford  mustang 1965  45  10000
volvo s80  1998  102  9850
ford  thundbd 2003  15  10500
chevy malibu 2000  50  3500
bmw 325i  1985  115  450
honda accord 2001  30  6000
ford taurus 2004  10  17000
toyota rav4 2002  180  750
chevy impala 1985  85  1550
ford explor 2003  25  9500

Missing pattern

A simple gawk program is

{ print }

This program consists of one program line that is an action. Because the pattern is missing, gawk selects all lines of input. When used without any arguments the print command displays each selected line in its entirety. This program copies the input to standard output.

$ gawk '{ print }' cars
plym  fury  1970  73   2500
Missing action

The next program has a pattern but no explicit action. The slashes indicate that Chevy is a regular expression.

/chevy/

In this case **gawk** selects from the input all lines that contain the string **chevy**. When you do not specify an **action**, **gawk** assumes that the action is **print**. The following example copies to standard output all lines from the input that contain the string **chevy**:

```
$ gawk '/chevy/' cars
chevy    malibu  1999    60      3000
chevy    malibu  2000    50      3500
chevy    impala  1985    85      1550
```

Single quotation marks

Although neither **gawk** nor shell syntax requires single quotation marks on the command line, it is still a good idea to use them because they can prevent problems. If the **gawk** program you create on the command line includes SPACE s or special shell characters, you must quote them. Always enclosing the program in single quotation marks is the easiest way of making sure that you have quoted any characters that need to be quoted.

Fields

The next example selects all lines from the file (it has no pattern). The braces enclose the action; you must always use braces to delimit the action so that **gawk** can distinguish it from the pattern. This example displays the third field ($3), a SPACE (the output field separator, indicated by the comma), and the first field ($1) of each selected line:

```
$ gawk '{print $3, $1}' cars
1970 plym
```
1999 chevy
1965 ford
1998 volvo
...

The next example, which includes both a **pattern** and an **action**, selects all lines that contain the string **chevy** and displays the third and first fields from the lines it selects:

```
$ gawk '/chevy/ {print $3, $1}' cars
1999 chevy
2000 chevy
1985 chevy
```

Next **gawk** selects lines that contain a match for the regular expression **h**. Because there is no explicit **action**, **gawk** displays all the lines it selects:

```
$ gawk '/h/' cars
chevy   malibu  1999    60      3000
ford    thundbd 2003    15      10500
chevy   malibu  2000    50      3500
honda   accord  2001    30      6000
chevy   impala  1985    85      1550
```

~ (matches operator)

The next **pattern** uses the matches operator (~) to select all lines that contain the letter **h** in the first field:

```
$ gawk '$1 ~ /h/' cars
chevy   malibu  1999    60      3000
chevy   malibu  2000    50      3500
honda   accord  2001    30      6000
chevy   impala  1985    85      1550
```
The caret (^) in a regular expression forces a match at the beginning of the line (page 830) or, in this case, the beginning of the first field:

```
$ gawk 's1 ~ /^h/' cars
```

```
honda    accord  2001    30      6000
```

Brackets surround a character-class definition (page 829). In the next example, `gawk` selects lines that have a second field that begins with t or m and displays the third and second fields, a dollar sign, and the fifth field. Because there is no comma between the "$" and the $5, `gawk` does not put a SPACE between them in the output.

```
$ gawk 's2 ~ /^[tm]/ {print $3, $2, "$" $5}' cars
```

```
1999 malibu $3000
1965 mustang $10000
2003 thundbd $10500
2000 malibu $3500
2004 taurus $17000
```

**Dollar signs**

The next example shows three roles a dollar sign can play in a `gawk` program. A dollar sign followed by a number names a field. Within a regular expression a dollar sign forces a match at the end of a line or field ($5). Within a string a dollar sign represents itself.

```
$ gawk 's3 ~ /$5/ {print $3, $1, "$" $5}' cars
```

```
1965 ford $10000
1985 bmw $450
1985 chevy $1550
```

In the next example, the equal-to relational operator (=) causes `gawk` to perform a numeric comparison between the third field in each line and the number 1985. The `gawk` command takes the default action, `print`, on each line where the comparison is true.

```
$ gawk 's3 == 1985' cars
```

```
bmw     325i    1985    115     450
```
The next example finds all cars priced at or less than $3,000:

```
$ gawk 'S5 <= 3000' cars
plym  fury  1970  73  2500
chevy malibu 1999  60  3000
bmw  325i 1985  115  450
toyota rav4 2002  180  750
chevy impala 1985  85  1550
```

**Textual comparisons**

When you use double quotation marks, `gawk` performs textual comparisons by using the ASCII (or other local) collating sequence as the basis of the comparison. In the following example, `gawk` shows that the strings `450` and `750` fall in the range that lies between the strings `2000` and `9000`, which is probably not the intended result:

```
$ gawk "2000" <= S5 && S5 < "9000" cars
plym  fury  1970  73  2500
chevy malibu 1999  60  3000
chevy malibu 2000  50  3500
bmw  325i 1985  115  450
honda accord 2001  30  6000
toyota rav4 2002  180  750
```

When you need to perform a numeric comparison, do not use quotation marks. The next example gives the intended result. It is the same as the previous example except that it omits the double quotation marks.

```
$ gawk '2000 <= S5 && S5 < 9000' cars
plym  fury  1970  73  2500
chevy malibu 1999  60  3000
chevy malibu 2000  50  3500
```
The range operator (,) selects a group of lines. The first line it selects is the one specified by the pattern before the comma. The last line is the one selected by the pattern after the comma. If no line matches the pattern after the comma, **gawk** selects every line through the end of the input. The next example selects all lines, starting with the line that contains **volvo** and concluding with the line that contains **bmw**:

```bash
$ gawk '/volvo/ , /bmw/' cars
volvo  s80     1998    102     9850
ford    thundbd 2003    15      10500
chevy   malibu  2000    50      3500
bmw     325i    1985    115     450
```

After the range operator finds its first group of lines, it begins the process again, looking for a line that matches the pattern before the comma. In the following example, **gawk** finds three groups of lines that fall between **chevy** and **ford**.

Although the fifth line of input contains **ford**, **gawk** does not select it because at the time it is processing the fifth line, it is searching for **chevy**.

```bash
$ gawk '/chevy/ , /ford/' cars
chevy  malibu  1999    60      3000
ford    mustang 1965    45      10000
chevy   malibu  2000    50      3500
bmw     325i    1985    115     450
honda   accord  2001    30      6000
ford    taurus  2004    10      17000
chevy   impala  1985    85      1550
ford    explor  2003    25      9500
```
When you are writing a longer *gawk* program, it is convenient to put the program in a file and reference the file on the command line. Use the `f` or `file` option followed by the name of the file containing the *gawk* program.

**BEGIN**

The following *gawk* program, stored in a file named `pr_header`, has two *actions* and uses the **BEGIN pattern**. The *gawk* utility performs the *action* associated with **BEGIN** before processing any lines of the data file: It displays a header. The second *action*, `{print}`, has no *pattern* part and displays all the lines from the input.

```bash
$ cat pr_header
BEGIN  {print "Make   Model   Year   Miles   Price"}
       {print}

$ gawk -f pr_header cars
Make   Model   Year   Miles   Price
plym    fury    1970    73      2500
chevy   malibu  1999    60      3000
ford    mustang 1965    45      10000
volvo   s80     1998    102     9850
...
```

The next example expands the *action* associated with the **BEGIN pattern**. In the previous and following examples, the whitespace in the headers is composed of single TABs, so that the titles line up with the columns of data.

```bash
$ cat pr_header2
BEGIN  {
    print "Make   Model   Year   Miles   Price"
    print "----------------------------------------"
}
       {print}

$ gawk -f pr_header2 cars
Make   Model   Year   Miles   Price
plex    fury    1970    73      2500
chevy   malibu  1999    60      3000
ford    mustang 1965    45      10000
volvo   s80     1998    102     9850
...
```
Make    Model    Year    Miles    Price
----------------------------------------
plym    fury    1970    73      2500
chevy   malibu  1999    60      3000
ford    mustang 1965    45      10000
volvo   s80     1998    102     9850
...

length function

When you call the **length** function without an argument, it returns the number of characters in the current line, including field separators. The **$0** variable always contains the value of the current line. In the next example, **gawk** prepends the line length to each line and then a pipe sends the output from **gawk** to **sort** (the **-n** option specifies a numeric sort; page 762) so that the lines of the **cars** file appear in order of length:

```
$ gawk '{print length, $0}' cars | sort -n
21 bmw  325i     1985    115     450
22 plym fury     1970    73      2500
23 volvo s80     1998    102     9850
24 ford explor   2003    25      9500
24 toyota rav4    2002    180     750
25 chevy impala  1985    85      1550
25 chevy malibu  1999    60      3000
25 chevy malibu  2000    50      3500
25 ford taurus  2004    10      17000
25 honda accord  2001    30      6000
26 ford mustang 1965    45      10000
26 ford thundbd 2003    15      10500
```

The formatting of this report depends on TAB s for horizontal alignment. The three extra characters at the beginning of each line throw off the format of several lines. A remedy for this situation is covered shortly.
NR (record number)

The NR variable contains the record (line) number of the current line. The following pattern selects all lines that contain more than 24 characters. The action displays the line number of each of the selected lines.

```
$ gawk 'length > 24 {print NR}' cars
2
3
5
6
8
9
11
```

You can combine the range operator ( , ) and the NR variable to display a group of lines of a file based on their line numbers. The next example displays lines 2 through 4:

```
$ gawk 'NR == 2 , NR == 4' cars
chevy   malibu  1999    60      3000
ford    mustang 1965    45      10000
volvo   s80     1998    102     9850
```

END

The END pattern works in a manner similar to the BEGIN pattern, except that gawk takes the actions associated with it after processing the last line of input. The following report displays information only after it has processed all the input. The NR variable retains its value after gawk finishes processing the data file, so that an action associated with an END pattern can use it:

```
$ gawk 'END {print NR, "cars for sale." }' cars
12 cars for sale.
```

The next example uses if control structures to expand the abbreviations used in some of the first fields. As long as gawk does not change a record, it leaves the entire record—including separators—intact. Once it makes a change to a record, gawk changes all separators in that record to the value of the output field separator. The default output field
separator is a SPACE.

```
$ cat separ_demo
{
  if ($1 ~ /ply/)  $1 = "plymouth"
  if ($1 ~ /chev/) $1 = "chevrolet"
  print
}
```

```
$ gawk -f separ_demo cars
plymouth fury 1970 73 2500
chevrolet malibu 1999 60 3000
ford mustang 1965 45 10000
volvo s80 1998 102 9850
ford thundbd 2003 15 10500
chevrolet malibu 2000 50 3500
bmw 325i 1985 115 450
honda accord 2001 30 6000
ford taurus 2004 10 17000
toyota rav4 2002 180 750
chevrolet impala 1985 85 1550
ford explor 2003 25 9500
```

**Stand-alone script**

Instead of calling `gawk` from the command line with the `-f` option and the name of the program you want to run, you can write a script that calls `gawk` with the commands you want to run. The next example is a stand-alone script that runs the same program as the previous example. The `#!/bin/gawk` if command (page 265) runs the `gawk` utility directly. You need both read and execute permission to the file holding the script (page 263).

```
$ chmod u+rx separ_demo2
```
$ cat separ_demo2

#!/bin/gawk -f

{ 
    if ($1 ~ /ply/) $1 = "plymouth"
    if ($1 ~ /chev/) $1 = "chevrolet"
    print
}

$ separ_demo2 cars

plymouth fury 1970 73 2500
chevrolet malibu 1999 60 3000
ford mustang 1965 45 10000
...

OFS variable

You can change the value of the output field separator by assigning a value to the OFS variable. The following example assigns a TAB character to OFS, using the backslash escape sequence \t. This fix improves the appearance of the report but does not line up the columns properly.

$ cat ofs_demo

BEGIN {OFS = "\t"}

{ 
    if ($1 ~ /ply/) $1 = "plymouth"
    if ($1 ~ /chev/) $1 = "chevrolet"
    print
}

$ gawk -f ofs_demo cars
plymouth    fury    1970    73      2500
chevrolet    malibu  1999    60      3000
ford    mustang 1965    45      10000
volvo    s80    1998    102     9850
ford    thundbd 2003    15     10500
chevrolet    malibu 2000    50     3500
bmw     325i    1985    115     450
honda    accord  2001    30     6000
ford    taurus  2004    10     17000
toyota    rav4  2002    180      750
chevrolet    impala 1985    85     1550
ford    explor  2003    25     9500

printf

You can use printf (page 534) to refine the output format. The following example uses a backslash at the end of several program lines to quote the following NEWLINE. You can use this technique to continue a long line over one or more lines without affecting the outcome of the program.

$ cat printf_demo
BEGIN   {
   print "                                 Miles"
   print "Make       Model       Year      (000)       Price"
   print \n   "--------------------------------------------------"
}
{
if ($1 ~ /ply/)  $1 = "plymouth"
if ($1 ~ /chev/) $1 = "chevrolet"
printf "%-10s %-8s    %2d   %5d     $ %8.2f
",
}
```bash
$ gawk -f printf_demo cars

Miles
Make       Model       Year      (000)       Price
--------------------------------------------------
plymouth   fury        1970      73     $ 2500.00
chevrolet  malibu      1999      60     $ 3000.00
ford       mustang     1965      45     $ 10000.00
volvo      s80         1998     102     $ 9850.00
ford       thundbd     2003      15     $ 10500.00
chevrolet  malibu      2000      50     $ 3500.00
bmw        325i        1985     115     $   450.00
honda      accord      2001      30     $ 6000.00
ford       taurus      2004      10     $ 17000.00
toyota     rav4        2002     180     $   750.00
chevrolet  impala      1985      85     $ 1550.00
ford       explor      2003      25     $  9500.00

Redirecting output

The next example creates two files: one with the lines that contain chevy and one with the lines that contain ford:

$ cat redirect_out
/chevy/   {print > "chevfile"}
/ford/    {print > "fordfile"}
```
END {print "done."}

$ gawk -f redirect_out cars
done.

$ cat chevfile
chevy  malibu  1999    60      3000
chevy  malibu  2000    50      3500
chevy  impala  1985    85      1550

The **summary** program produces a summary report on all cars and newer cars. Although they are not required, the initializations at the beginning of the program represent good programming practice; **gawk** automatically declares and initializes variables as you use them. After reading all the input data, **gawk** computes and displays averages.

$ cat summary
BEGIN {
    yearsum = 0 ; costsum = 0
    newcostsum = 0 ; newcount = 0
}
{
    yearsum += $3
    costsum += $5
}
$3 > 2000 {newcostsum += $5 ; newcount ++}
END {
    printf "Average age of cars is %.1f years\n",
          2006 - (yearsum/NR)
    printf "Average cost of cars is $%.2f\n",
            costsum/NR
printf "Average cost of newer cars is $%7.2f\n",
    newcostsum/newcount
}

$ awk -f summary cars
Average age of cars is 13.1 years
Average cost of cars is $6216.67
Average cost of newer cars is $8750.00

The following \texttt{gawk} command shows the format of a line from the \texttt{passwd} file that the next example uses:

$ awk '/mark/ \{print\}' /etc/passwd
mark:x:107:100:ext 112:/home/mark:/bin/tcsh

The next example demonstrates a technique for finding the largest number in a field. Because it works with the \texttt{passwd} file, which delimits fields with colons (:), the example changes the input field separator (FS) before reading any data. It reads the \texttt{passwd} file and determines the next available user ID number (field 3). The numbers do not have to be in order in the \texttt{passwd} file for this program to work.

The \textit{pattern} ($3 > \texttt{saveit}$) causes \texttt{gawk} to select records that contain a user ID number greater than any previous user ID number that it has processed. Each time it selects a record, \texttt{gawk} assigns the value of the new user ID number to the \texttt{saveit} variable. Then \texttt{gawk} uses the new value of \texttt{saveit} to test the user IDs of all subsequent records. Finally \texttt{gawk} adds 1 to the value of \texttt{saveit} and displays the result.

$ cat find_uid
BEGIN        \{FS = ":"\}
      \{saveit = 0\}
$3 > \texttt{saveit} \{\texttt{saveit} = $3\}
END           \{print "Next available UID is " \texttt{saveit} + 1\}

$ awk -f find_uid /etc/passwd
Next available UID is 192
The next example produces another report based on the `cars` file. This report uses nested `if...else` control structures to substitute values based on the contents of the price field. The program has no `pattern` part; it processes every record.

```
$ cat price_range
{
    if             ($5 <= 5000)               $5 = "inexpensive"
    else if    (5000 < $5 && $5 < 10000)  $5 = "please ask"
    else if    (10000 <= $5)              $5 = "expensive"
    
    #
    printf "%-10s %-8s    %2d    %5d    %-12s\n",\n    $1, $2, $3, $4, $5
}
```

```
$ gawk -f price_range cars

Associative arrays
Next the **manuf** associative array uses the contents of the first field of each record in the **cars** file as an index. The array is composed of the elements **manuf[plym]**, **manuf[chevy]**, **manuf[ford]**, and so on. Each new element is initialized to 0 (zero) as it is created. The C language operator `++` increments the variable that it follows.

The **action** following the **END pattern** is the special **for** structure that loops through the elements of an associative array. A pipe sends the output through **sort** to produce an alphabetical list of cars and the quantities in stock. Because it is a shell script and not a **gawk** program file, you must have both read and execute permission to the **manuf** file to execute it as a command. Depending on how the **PATH** variable (page 284) is set, you may have to execute the script as `./manuf`.

```
$ cat manuf

gawk ' {manuf[$1]++}

END   {for (name in manuf) print name, manuf[name]}

' cars |
sort

$ manuf

bmw 1
chevy 3
ford 4
honda 1
plym 1
toyota 1
volvo 1
```

The next program, named **manuf.sh**, is a more general shell script that includes some error checking. This script lists and counts the contents of a column in a file, with both the column number and the name of the file being specified on the command line.

The first **action** (the one that starts with `{count}`) uses the shell variable `$1` in the middle of the **gawk** program to specify an array index. Because of the way the single quotation marks are paired, the `$1` that appears to be within single quotation marks is actually not quoted: The two quoted strings in the **gawk** program surround, but do not include, the `$1`. Because the `$1` is not quoted, and because this is a shell script, the shell substitutes the value of the first command line argument in place of `$1` (page 481). As a result the `$1` is interpreted before the **gawk** command is invoked. The leading dollar sign (the one before the first single quotation mark on that line) causes **gawk** to interpret what the shell substitutes as a field number.
```bash
$ cat manuf.sh
if [ $# != 2 ]
    then
        echo "Usage: manuf.sh field file"
        exit 1
fi
gawk < $2 '    {count['$1']++}    END {for (item in count) printf "%-20s%-20s\n", item, count[item]}' | sort

$ manuf.sh
Usage: manuf.sh field file

$ manuf.sh 1 cars
bmw 1
chevy 3
ford 4
honda 1
plym 1
toyota 1
volvo 1

$ manuf.sh 3 cars
1965 1
1970 1
```
A way around the tricky use of quotation marks that allow parameter expansion within the `gawk` program is to use the `\v` option on the command line to pass the field number to `gawk` as a variable. This change makes it easier for someone else to read and debug the script. You call the `manuf2.sh` script the same way you call `manuf.sh`:

```
$ cat manuf2.sh
if [ $# != 2 ]
    then
        echo "Usage: manuf.sh field file"
        exit 1
fi
gawk -v "field=$1" < $2
    {count[$field]++}
END
    {for (item in count) printf "%-20s%-20s\n",
        item, count[item]}' | sort
```

The `word_usage` script displays a word usage list for a file you specify on the command line. The TR utility (page 804) lists the words from standard input, one to a line. The `sort` utility orders the file, with the most frequently used words first. This script sorts groups of words that are used the same number of times in alphabetical order.

```
$ cat word_usage
tr -cs 'a-zA-Z' '^[\n*]'$ < $1 |
```
gawk

    {count[$1]++}
END   {for (item in count) printf "%-15s%3s\n", item, count[item]}' |
sort +1nr +0f -1

$ word_usage textfile

the             42
file            29
fsck            27
system          22
you             22
to              21
it              17
SIZE            14
and             13
MODE            13
...

Following is a similar program in a different format. The style mimics that of a C program and may be easier to read and work with for more complex gawk programs:

$ cat word_count

tr -cs 'a-zA-Z' '[:\n*]' < $1 |
gawk ' {
    count[$1]++
}
END   {
    for (item in count)
        {

if (count[item] > 4)
{
    printf "%-15s%3s\n", item, count[item]

}
}

} | sort +1nr +0f -1

The `tail` utility displays the last ten lines of output, illustrating that words occurring fewer than five times are not listed:

```
$ word_count textfile | tail
directories      5
if               5
information      5
INODE            5
more             5
no               5
on               5
response         5
this             5
will             5
```

The next example shows one way to put a date on a report. The first line of input to the `gawk` program comes from `date`. The program reads this line as record number 1 (`NR == 1`), processes it accordingly, and processes all subsequent lines with the `action` associated with the next `pattern` (`NR > 1`).

```
$ cat report
if (test $# = 0) then
    echo "You must supply a filename."
```
```bash
exit 1
fi
(date; cat $1) |
gawk 'NR == 1 {print "Report for", $1, $2, $3 "", " $6} NR > 1 {print $5 "\t" $1}'

$ report cars
Report for Mon Jan 31, 2005
2500 plym
3000 chevy
10000 ford
9850 volvo
10500 ford
3500 chevy
450 bmw
6000 honda
17000 ford
750 toyota
1550 chevy
9500 ford

The next example sums each of the columns in a file you specify on the command line; it takes its input from the numbers file. The program performs error checking, reporting on and discarding rows that contain nonnumeric entries. It uses the next command (with the comment skip bad records) to skip the rest of the commands for the current record if the record contains a nonnumeric entry. At the end of the program, gawk displays a grand total for the file.

optional: Advanced Gawk Programming

This section discusses some of the advanced features that the GNU developers added when they rewrote awk to create gawk. It covers how to control input using the getline statement, how to use a coprocess to exchange information between gawk and a program running in the background, and how to use a coprocess to exchange data over a network.

getline: CONTROLLING INPUT

The getline statement gives you more control over the data gawk reads than other methods of input do. When you give a variable name as an argument to getline, it reads data into that variable. The BEGIN block of the g1 program uses getline to read one line into the variable aa from standard input:

```
$ cat g1  
BEGIN   {  
    getline aa  
    print aa  
}  
$ echo aaaa | gawk -f g1  
aaaa
```

The alpha file is used in the next few examples:

```
$ cat alpha  
nnnnnnnnnn
bbbbbbbbbb
cccccccccc
dddddddddd
```

Even when g1 is given more than one line of input, it processes only the first line:

```
$ gawk -f g1 < alpha  
nnnnnnnnnn
```
When `getline` is not given an argument, it reads into `$0` and modifies the field variables ($1, $2, . . .):

```
$ gawk 'BEGIN {getline;print $1}' < alpha

aaaaaaaaa
```

The `g2` program uses a `while` loop in the `BEGIN` block to loop over the lines in standard input. The `getline` statement reads each line into `holdme` and `print` outputs each value of `holdme`.

```
$ cat g2
BEGIN {
    while (getline holdme)
        print holdme
}
$ gawk -f g2 < alpha

aaaaaaaaa
bbbbbbbbb
ccccccccc
dddddddddd
```

The `g3` program demonstrates that `gawk` automatically reads each line of input into `$0` when it has statements in its body (and not just a `BEGIN` block). This program outputs the record number (`NR`), the string `$0:`, and the value of `$0` (the current record) for each line of input.

```
$ cat g3
    {print NR, "$0:", $0}

$ gawk -f g3 < alpha

1 $0: aaaaaaaaaa
2 $0: bbbbbbbbb
```
Next `g4` demonstrates that `getline` works independently of `gawk`'s automatic reads and `$0`. When `getline` reads into a variable, it does not modify `$0` nor does it modify any of the fields in the current record ($1, $2, ...). The first statement in `g4` is the same as the statement in `g3` and outputs the line that `gawk` has automatically read. The `getline` statement reads the next line of input into the variable named `aa`. The third statement outputs the record number, the string `aa:`, and the value of `aa`. The output from `g4` shows that `getline` processes records independently of `gawk`'s automatic reads.

```bash
$ cat g4
{
   print NR, "$0: ", $0
   getline aa
   print NR, "aa: ", aa
}

$ gawk -f g4 < alpha
1 $0: aaaaaaaaa
2 aa: bbbbbbbbb
3 $0: cccccccccc
4 aa: ddddddddd
```

The `g5` program outputs each line of input except that it skips lines that begin with the letter `b`. The first `print` statement outputs each line that `gawk` reads automatically. Next the `/^b/ pattern` selects all lines that begin with `b` for special processing. The `action` uses `getline` to read the next line of input into the variable `hold`, outputs the string `skip this line:` followed by the value of `hold`, and outputs the value of `$1`. The `$1` holds the value of the first field of the record that `gawk` read automatically, not the record read by `getline`. The final statement displays a string and the value of `NR`, the current record number. Even though `getline` does not change `$0` when it reads into a variable, `gawk` increments `NR`.

```bash
$ cat g5
   # print all lines except those read with getline
```
{print "line ", NR, $0}

# if line begins with "b" process it specially
/^b/ {
    # use getline to read the next line into variable named hold
    getline hold

    # print value of hold
    print "skip this line:", hold

    # $0 is not affected when getline reads into a variable
    # $1 still holds previous value
    print "previous line began with:", $1
}

{
    print ">>>> finished processing line ", NR
    print ""
}

$ gawk -f g5 < alpha

line # 1 aaaaaaaaa

>>>> finished processing line # 1

line # 2 bbbbbbbbb

COPROCESS: TWO-WAY I/O

A coprocess is a process that runs in parallel with another process. Starting with version 3.1, gawk can invoke a coprocess to exchange information directly with a background process. A coprocess can be useful when you are working in a client/server environment, setting up an SQL (902) front end/back end, or exchanging data with a remote system over a network. The gawk syntax identifies a coprocess by preceding the name of the program that starts the background process with a |& operator.

The coprocess command must be a filter (i.e., it reads from standard input and writes to standard output) and must flush its output whenever it has a complete line rather than accumulating lines for subsequent output. When a command is invoked as a coprocess, it is connected via a two-way pipe to a gawk program so that you can read from and write to the coprocess.

to_upper

When used alone the TR utility (page 804) does not flush its output after each line. The to_upper shell script is a wrapper for tr that does flush its output; this filter can be run as a coprocess. For each line read, to_upper writes the line, translated to uppercase, to standard output. Remove the # before set -x if you want to_upper to display debugging output.

$ cat to_upper
#!/bin/bash
#set -x
while read arg
do
  echo "$arg" | tr '[a-z]' '[A-Z]'
done

$ echo abcdef | to_upper
The `g6` program invokes `to_upper` as a coprocess. This `gawk` program reads standard input or a file specified on the command line, translates the input to uppercase, and writes the translated data to standard output.

```bash
$ cat g6
{
    print $0 | "to_upper"
    "to_upper" | getline hold
    print hold
}

$ gawk -f g6 < alpha
AAAAAAA
BBBBBBB
CCCCCCC
DDDDDDD
```

The `g6` program has one compound statement, enclosed within braces, comprising three statements. Because there is no pattern, `gawk` executes the compound statement once for each line of input.

In the first statement, `print $0` sends the current record to standard output. The `|&` operator redirects standard output to the program named `to_upper`, which is running as a coprocess. The quotation marks around the name of the program are required. The second statement redirects standard output from `to_upper` to a `getline` statement, which copies its standard input to the variable named `hold`. The third statement, `print hold`, sends the contents of the `hold` variable to standard output.

**GETTING INPUT FROM A NETWORK**

Building on the concept of a coprocess, `gawk` can exchange information with a process on another system via an IP network connection. When you specify one of the special filenames that begins with `/inet/`, `gawk` processes your request using a network connection. The format of these special filenames is

```
/inet/protocol/local-port/remote-host/remote-port
```
where **protocol** is usually tcp but can be udp, **local-port** is 0 (zero) if you want gawk to pick a port (otherwise it is the number of the port you want to use), **remote-host** is the IP address (page 882) or fully qualified domain name (page 876) of the remote host, and **remote-port** is the port number on the remote host. Instead of a port number in **local-port** and **remote-port**, you can specify a service name such as http or ftp.

The **g7** program reads the **cars** file from the server at **www.sobell.com**; the author has set up this file for you to experiment with. On **www.sobell.com** the file is located at `/CMDREF1/code/chapter_12/cars`. The first statement in **g7** assigns the special filename to the **server** variable. The filename specifies a TCP connection, allows the local system to select an appropriate port, and connects to **www.sobell.com** on port 80. You can use http in place of **80** to specify the standard HTTP port.

The second statement uses a coprocess to send a GET request to the remote server. This request includes the pathname of the file gawk is requesting. A while loop uses a coprocess to redirect lines from the server to getline. Because getline has no variable name as an argument, it saves its input in the current record buffer $0. The final print statement sends each record to standard output.

Experiment with this script, replacing the final print statement with gawk statements that process the file.

```
$ cat g7
BEGIN   {
    # set variable named server
    # to special networking filename
    server = "/inet/tcp/0/www.sobell.com/80"

    # use coprocess to send GET request to remote server
    print "GET /CMDREF1/code/chapter_12/cars" |& server

    # while loop uses coprocess to redirect
    # output from server to getline
    while (server |& getline)
        print $0
}
```
$ gawk -f g7
plym  fury  1970  73    2500
chevy malibu 1999  60    3000
ford mustang 1965  45    10000
volvo s80 1998 102   9850
...
Error Messages

The following examples show some of the more common causes of `gawk` error messages (and nonmessages). These examples are run under `bash`. When you use `gawk` with `tcsh`, the error messages from the shell will be different.

The first example leaves the single quotation marks off the command line, so the shell interprets `$3` and `$1` as shell variables. Also, because there are no single quotation marks, the shell passes `gawk` four arguments instead of two.

```
$ gawk {print $3, $1} cars
```

```
gawk: cmd. line:2: (END OF FILE)
gawk: cmd. line:2: syntax error
```

The next command line includes a typo (`prinnt`) that `gawk` does not catch. Instead of issuing an error message, `gawk` simply does not do anything useful.

```
$ gawk '$3 >= 83 {prinnt $1}' cars
```

The next example has no braces around the `action`:

```
$ gawk '/chevy/ print $3, $1' cars
```

```
gawk: cmd. line:1: /chevy/ print $3, $1
gawk: cmd. line:1: ^ syntax error
```

There is no problem with the next example; `gawk` did just what you asked it to do (none of the lines in the file contains a `z`).

```
$ gawk '/z/' cars
```

The next example shows an improper `action` for which `gawk` does not issue an error message:

```
$ gawk '{{$3 " made by " $1}'} cars
```

The following example does not display the heading because there is no backslash after the `print` command in the `BEGIN` block. The backslash is needed to quote the following NEWLINE so that the line can be continued. Without it, `gawk` sees two separate statements; the second does nothing.

```
$ cat print_cars
```
BEGIN {print
"Model Year Price"
/chevy/ {printf "%5s\t%4d\t%5d\n", $2, $3, $5}
$ gawk -f print_cars cars

malibu 1999  3000
malibu 2000  3500
impala 1985  1550

You must use double quotation marks, not single ones, to delimit strings.

$ cat print_cars2
BEGIN {OFS='\t'}
$3 ~ /5$/  {print $3, $1, "$" $5}

$ gawk -f print_cars2 cars
gawk: print_cars2:1: BEGIN {OFS='\t'}
gawk: print_cars2:1: ^ invalid char '"' in expression
Chapter Summary

The `gawk` utility is a pattern-scanning and processing language that searches one or more files to see whether they contain records (usually lines) that match specified patterns. It processes lines by performing actions, such as writing the record to standard output or incrementing a counter, each time it finds a match.

A `gawk program` consists of one or more lines containing a `pattern` and/or `action` in the following format:

```
pattern { action }
```

The `pattern` selects lines from the input. The `gawk` utility performs the `action` on all lines that the `pattern` selects. If a `program` line does not contain a `pattern`, `gawk` selects all lines in the input. If a program line does not contain an `action`, `gawk` copies the selected lines to standard output.

A `gawk` program can use variables, functions, arithmetic operators, associative arrays, control statements, and C's `printf` statement. Advanced `gawk` programming takes advantage of `getline` statements to fine-tune input, coprocesses to enable `gawk` to exchange data with other programs, and network connections to exchange data with programs running on remote systems on a network.
Exercises

1. Write a gawk program that numbers each line in a file and sends its output to standard output.

2. Write a gawk program that displays the number of characters in the first field followed by the first field and sends its output to standard output.

3. Write a gawk program that uses the cars file (page 537), displays all cars priced at more than $5000, and sends its output to standard output.

4. Use gawk to determine how many lines in /etc/termcap contain the string vt100. Verify your answer using grep.
Advanced Exercises

5. Experiment with pgawk. What does it do? How can it be useful?

6. Write a gawk program named net_list that reads from the cars file on www.sobell.com (see "Getting Input from a Network" on page 558) and displays a list of each of the cars' make, model, and price. Separate the output fields with TABs.

7. Expand the net_list program developed in exercise 6 to use to_upper (page 557) as a coprocess to display the list of cars with only the make of the cars in uppercase. The model and subsequent fields on each line should appear as they do in the cars file.

8. How can you get gawk to neatly format—that is "pretty print"—a gawk program file? (Hint: See the gawk man page.)
Chapter 13. The **sed** Editor

IN THIS CHAPTER

Syntax 564

Arguments 564

Options 564

Addresses 565

Instructions 566

Control Structures 567

The Pattern Space and the Hold Space 568

Examples 568

The **sed** (stream editor) utility is a batch (noninteractive) editor. It transforms an input stream that can come from a file or standard input. It is frequently used as a filter in a pipe. Because it makes only one pass through its input, **sed** is more efficient than an interactive editor such as **ed**. This chapter describes GNU **sed**.
Syntax

A `sed` command line has the following syntax:

```
    sed [\n] [program] [\n] [file-list]
```

```
    sed [\n] [f] [program-file] [\n] [file-list]
```

The `sed` utility takes its input from files you specify on the command line or from standard input. Unless you direct output from `sed` elsewhere, it goes to standard output.
Arguments

The program is a sed program that is included on the command line. This format allows you to write simple, short sed programs without creating a separate program-file. The program-file is the pathname of a file containing a sed program (see "Editor Basics"). The file-list contains pathnames of the ordinary files that sed processes. These are the input files. When you do not specify a file, sed takes its input from standard input.
## Options

- **-f program-file**
  
  Causes `sed` to read its program from the file named `program-file` instead of from the command line. You can use this option more than once on the command line.

- **-i [suffix]**
  
  Edits files in place. Without this option `sed` sends its output to standard output. With this option `sed` replaces the file it is processing with its output. When you specify a `suffix`, `sed` makes a backup of the original file. This backup has the original filename with `suffix` appended. You must include a period in `suffix` if you want a period to appear between the original filename and `suffix`.

- **-h** or **-help**
  
  Summarizes how to use `sed`.

- **-n** or **-quiet** or **-silent**
  
  Causes `sed` not to copy lines to standard output except as specified by the Print (`p`) instruction or flag.
Editor Basics

A **sed** program consists of one or more lines with the following syntax:

```
[ address
  , address
] ]
instruction
[ argument-list
]
```

The *addresses* are optional. If you omit the *address*, **sed** processes all lines from the input. The *instruction* is the editing instruction that modifies the text. The *addresses* select the line(s) that the *instruction* part of the command operates on. The number and kinds of arguments in the *argument-list* depend on the *instruction*. If you want to put several **sed** commands on one line you can separate the commands with semicolons (;).

The **sed** utility processes input as follows:

1. Reads one line of input from *file-list* or standard input.

2. Reads the first instruction from the *program* or *program-file*. If the *address*(es) select the input line, acts on the input line as the *instruction* specifies.

3. Reads the next instruction from the *program* or *program-file*. If the *address*(es) select the input line, acts on the input line (possibly modified by the previous instruction) as the *instruction* specifies.

4. Repeats step 3 until it has executed all instructions in the *program* or *program-file*.

5. Starts over again with step 1 if there is another line of input; otherwise, it is finished.

Addresses

A line number is an address that selects a line. As a special case, the line number $ represents the last line of input.

A regular expression (refer to Appendix A) is an address that selects those lines containing a string that the regular expression matches. Although slashes are often used to delimit these regular expressions, **sed** permits you to use any character other than a backslash or NEWLINE for this purpose.

Except as noted, zero, one, or two addresses (either line numbers or regular expressions) can precede an instruction. If you do not use an address, **sed** selects all lines, causing the instruction to act on every line of input. Providing one address causes the instruction to act on each input line that the address selects. Providing two addresses causes the instruction to act on groups of lines. The first address selects the first line in the first group. The second address selects the next subsequent line that it matches; this line is the last line in the first group. If no match for the second address is found, the second address points to the end of the file. After selecting the last line in a group, **sed** starts the selection process over again, looking for the next line that the first address matches. This line is the first line in the next group. The **sed** utility continues this process until it has finished going through the entire file.

Instructions
**d (delete)** The Delete instruction causes `sed` not to write out the lines it selects and not to finish processing the lines. After `sed` executes a Delete instruction, it reads the next input line and begins over again with the first instruction from the program or program-file.

**n (next)** The Next instruction writes out the currently selected line if appropriate, reads the next input line, and starts processing the new line with the next instruction from the program or program-file.

**a (append)** The Append instruction appends one or more lines to the currently selected line. If you precede an Append instruction with two addresses, it appends to each line that is selected by the addresses; earlier versions of `sed` did not accept Append instructions with two addresses. If you do not precede an Append instruction with an address, it appends to each input line. An Append instruction has the following format:

```
[address
 [,address]] a\text \text ...
text
```

You must end each line of appended text, except the last, with a backslash (the backslash quotes the following NEWLINE). The appended text concludes with a line that does not end with a backslash. The `sed` utility always writes out appended text, regardless of whether you use a `n` flag on the command line. It even writes out the text if you delete the line to which you are appending the text.

**i (insert)** The Insert instruction is identical to the Append instruction except that it places the new text before the selected line.

**c (change)** The Change instruction is similar to Append and Insert except that it changes the selected lines so that they contain the new text. When you specify an address range, Change replaces the entire range of lines with a single occurrence of the new text.

**s (substitute)** The Substitute instruction in `sed` is similar to that in `vim` (page 166). It has the following format:

```
[address
 [,address]] s/
 pattern/replacement-string 
/[g][p][w
 file
 ]
```

The `pattern` is a regular expression (refer to Appendix A) that is delimited by any character other than a SPACE or NEWLINE, traditionally a slash (`/`). The `replacement-string` starts immediately following the second delimiter and must be terminated by the same delimiter. The final (third) delimiter is required. The `replacement-string` can contain an ampersand (`&`), which `sed` replaces with the matched `pattern`. Unless you use the `g` flag, the Substitute instruction replaces only the first occurrence of the `pattern` on each selected
The **g** (global) flag causes the Substitute instruction to replace all nonoverlapping occurrences of the *pattern* on the selected lines.

The **p** (print) flag causes **sed** to send all lines on which it makes substitutions to standard output. This flag overrides the `n` option on the command line.

The **w** (write) flag is similar to the **p** flag but it sends its output to the file specified by *file*. A single SPACE and the name of the output file must follow a **w** flag.

p  (print) The Print instruction writes the selected lines to standard output, writing the lines immediately, and does not reflect the effects of subsequent instructions. This instruction overrides the `n` option on the command line. (The `n` option prevents **sed** from copying lines to standard output.)

w file (write) This instruction is similar to the Print instruction except that it sends output to the file specified by *file*. A single SPACE and the name of the output file must follow a Write instruction.

r file (read) The Read instruction reads the contents of the specified file and appends it to the selected line. A single SPACE and the name of the input file must follow a Read instruction.

q  (quit) The Quit instruction causes **sed** to terminate immediately.

**Control Structures**

!  (NOT) Causes **sed** to apply the following instruction, located on the same line, to each of the lines not selected by the address portion of the instruction. For example, `3!d` deletes all lines except line 3 and `$!p` displays all lines except the last.

{} (group instructions) When you enclose a group of instructions within a pair of braces, a single address (or address pair) selects the lines on which the group of instructions operates. Use semicolons (;) to separate multiple commands appearing on a single line.

**Branch instructions**

The **sed info** page lists the branch instructions as "Commands for **sed** gurus" and suggests that if you need them you might be better off writing your program in **awk** or **Perl**.

: *label* Identifies a location within a **sed** program. The *label* is useful as a target for the **b** and **t** branch instructions.

b [*label*] Unconditionally transfers control (branches) to *label*. Without *label*, skips the rest of the instructions for the current line of input and reads the next line of input (page 565).

t [*label*] Transfers control (branches) to *label* only if a Substitute instruction has been successful since the most recent line of input was read (conditional branch). Without *label*, skips the rest of the instructions for the current line of input and reads the next line of input (page 565).

**The Pattern Space and the Hold Space**

The **sed** utility has two buffers. The commands reviewed up to this point work with the *Pattern space*, which initially holds the line of input that **sed** just read. The *Hold space* can hold data while you manipulate data in the Pattern space; it is a temporary buffer. Until you place data in the Hold space it is empty. This section discusses commands that move data between the Pattern space and the Hold space.

g  Copies the contents of the Hold space to the Pattern space. The original contents of the Pattern space is lost.

G  Appends a NEWLINE and the contents of the Hold space to the Pattern space.

h  Copies the contents of the Pattern space to the Hold space. The original contents of the Hold space is lost.
H Appends a NEWLINE and the contents of the Pattern space to the Hold space.
X Exchanges the contents of the Pattern space and the Hold space.
Examples

new data file  The following examples use the input file new:

$ cat new
Line one.
The second line.
The third.
This is line four.
Five.
This is the sixth sentence.
This is line seven.
Eighth and last.

Unless you instruct it not to, sed sends all lines—selected or not—to standard output. When you use the in option on the command line, sed sends only certain lines, such as those selected by a Print (p) instruction, to standard output.

The following command line displays all the lines in the new file that contain the word line (all lowercase). In addition, because there is no in option, sed displays all the lines of input. As a result the lines that contain the word line are displayed twice.

$ sed '/line/ p' new
Line one.
The second line.
The second line.
The third.
This is line four.
This is line four.
Five.
This is the sixth sentence.
This is line seven.
This is line seven.
Eighth and last.

The command uses the address `/line/`, a regular expression that is a simple string. The `sed` utility selects each of the lines that contains a match for that pattern. The Print (`p`) instruction displays each of the selected lines.

The following command uses the `-n` option so that `sed` displays only the selected lines:

```
$ sed -n '/line/ p' new
```

The second line.

This is line four.

This is line seven.

Next `sed` displays part of a file based on line numbers. The Print instruction selects and displays lines 3 through 6.

```
$ sed -n '3,6 p' new
```

The third.

This is line four.

Five.

This is the sixth sentence.

The next command line uses the Quit instruction to cause `sed` to display only the beginning of a file. In this case `sed` displays the first five lines of `new` just as a `head 5 new` command would.

```
$ sed '5 q' new
```

Line one.

The second line.

The third.

This is line four.

Five.

When you need to give `sed` more complex or lengthy instructions, you can use a `program-file`. The `print3_6`
When you need to give `sed` more complex or lengthy instructions, you can use a program-file. The `print3_6` program performs the same function as the command line in a previous example. The `-f` option tells `sed` that it should read its program from the file named on the command line.

```
$ cat print3_6
3,6 p

$ sed -n -f print3_6 new
The third.
This is line four.
Five.
This is the sixth sentence.
```

**Append**

The next program selects line 2 and uses an Append instruction to append a NEWLINE and the text `AFTER` to the selected line. Because the command line does not include the `-n` option, `sed` copies all the lines from the input file `new`.

```
$ cat append_demo
2 a
AFTER.

$ sed -f append_demo new
Line one.
The second line.
AFTER.
The third.
This is line four.
Five.
This is the sixth sentence.
This is line seven.
```
Eighth and last.

Insert

The `insert_demo` program selects all the lines containing the string `This` and inserts a NEWLINE and the text `BEFORE.` before the selected lines.

```
$ cat insert_demo
/This/ i\
BEFORE.

$ sed -f insert_demo new
Line one.
The second line.
The third.
BEFORE.
This is line four.
Five.
BEFORE.
This is the sixth sentence.
BEFORE.
This is line seven.
Eighth and last.
```

Change

The next example demonstrates a Change instruction with an address range. When you specify a range of lines for a Change instruction, it does not change each line within the range but rather changes the block of lines to a single occurrence of the new text.

```
$ cat change_demo
```
SED WILL INSERT THESE
THREE LINES IN PLACE
OF THE SELECTED LINES.

$ sed -f change_demo new
Line one.

SED WILL INSERT THESE
THREE LINES IN PLACE
OF THE SELECTED LINES.
Five.
This is the sixth sentence.
This is line seven.
Eighth and last.

Substitute

The next example demonstrates a Substitute instruction. The sed utility selects all lines because the instruction has no address. On each line subs_demo replaces the first occurrence of line with sentence. The p flag displays each line where a substitution occurs. The command line calls sed with the in option, so sed displays only the lines that the program explicitly requests it to display.

$ cat subs_demo
s/line/sentence/p

$ sed -n -f subs_demo new
The second sentence.
This is sentence four.
This is sentence seven.

The next example is similar to the preceding one except that a w flag and filename (temp) at the end of the
Substitute instruction cause `sed` to create the file named `temp`. The command line does not include the `-n` option, so it displays all lines in addition to writing the changed lines to `temp`. The `cat` utility displays the contents of the file `temp`. The word Line (starting with an uppercase L) is not changed.

```bash
$ cat write_demo1
s/line/sentence/w temp

$ sed -f write_demo1 new
Line one.
The second sentence.
The third.
This is sentence four.
Five.
This is the sixth sentence.
This is sentence seven.
Eighth and last.

$ cat temp
The second sentence.
This is sentence four.
This is sentence seven.
```

The following `bash` script changes all occurrences of `REPORT` to `report`, `FILE` to `file`, and `PROCESS` to `process` in a group of files. Because it is a shell script and not a `sed` program file, you must have read and execute permission to the `sub` file to execute it as a command (page 263). The `for` structure (page 451) loops through the list of files supplied on the command line. As it processes each file, the script displays each filename before processing the file with `sed`. This program uses multiline embedded `sed` commands. Because the NEWLINEs between the commands are quoted (placed between single quotation marks), `sed` accepts multiple commands on a single, extended command line (within a shell script). Each Substitute instruction includes a `g` (global) flag to take care of the case where a string occurs more than one time on a line.

```bash
$ cat sub
for file
```
do
  
  echo $file

  mv $file $$.subhld

  sed 's/REPORT/report/g
       s/FILE/file/g
       s/PROCESS/process/g' $$.subhld > $file

done

rm $$.subhld

$ sub file1 file2 file3

file1
file2
file3

In the next example, a Write instruction copies part of a file to another file (temp2). The line numbers 2 and 4, separated by a comma, select the range of lines sed is to copy. This program does not alter the lines.

$ cat write_demo2

2,4 w temp2

$ sed -n -f write_demo2 new

$ cat temp2

The second line.
The third.
This is line four.

The program write_demo3 is very similar to write_demo2 but precedes the Write instruction with the NOT operator (!), causing sed to write to the file those lines not selected by the address.
$ cat write_demo3

2,4 !w temp3

$ sed -n -f write_demo3 new

$ cat temp3

Line one.
Five.
This is the sixth sentence.
This is line seven.
Eighth and last.

The following example demonstrates the Next instruction. When it processes the selected line (line 3), sed immediately starts processing the next line without displaying line 3.

$ cat next_demo1

3 n
p

$ sed -n -f next_demo1 new

Line one.
The second line.
This is line four.
Five.
This is the sixth sentence.
This is line seven.
Eighth and last.

The next example uses a textual address. The sixth line contains the string the, so the Next instruction causes sed
not to display it.

```
$ cat next_demo2
/the/ n
p
```

```
$ sed -n -f next_demo2 new
Line one.
The second line.
The third.
This is line four.
Five.
This is line seven.
Eighth and last.
```

The next set of examples uses the file `compound.in` to demonstrate how `sed` instructions work together.

```
$ cat compound.in
1. The words on this page...
2. The words on this page...
3. The words on this page...
4. The words on this page...
```

The following example substitutes the string `words` with `text` on lines 1, 2, and 3 and the string `text` with `TEXT` on lines 2, 3, and 4. The example also selects and deletes line 3. The result is `text` on line 1, `TEXT` on line 2, no line 3, and `words` on line 4. The `sed` utility made two substitutions on lines 2 and 3: `text` for `words` and `TEXT` for `text`. Then `sed` deleted line 3.

```
$ cat compound
1,3 s/words/text/
2,4 s/text/TEXT/
```
The ordering of instructions within a `sed` program is critical. Both Substitute instructions are applied to the second line in the following example, as in the previous example, but the order in which the substitutions occur changes the result.

```
$ sed -f compound compound.in
1. The text on this page...
2. The TEXT on this page...
3. The words on this page...

The ordering of instructions within a `sed` program is critical. Both Substitute instructions are applied to the second line in the following example, as in the previous example, but the order in which the substitutions occur changes the result.

$ cat compound2
2,4 s/text/TEXT/
1,3 s/words/text/
3 d

$ sed -f compound2 compound.in
1. The text on this page...
2. The text on this page...
3. The words on this page...

Next `compound3` appends two lines to line 2. The `sed` utility displays all the lines from the file once because no `in` option appears on the command line. The Print instruction at the end of the program file displays line 3 an additional time.

$ cat compound3
2 a\ 
This is line 2a.\ 
This is line 2b.
3 p
$ sed -f compound3 compound.in
1. The words on this page...

This is line 2a.
This is line 2b.

3. The words on this page...

4. The words on this page...

The next example shows that `sed` always displays appended text. Here line 2 is deleted but the Append instruction still displays the two lines that were appended to it. Appended lines are displayed even if you use the `-n` option on the command line.

$ cat compound4
2 a\
This is line 2a.\nThis is line 2b.
2 d

$ sed -f compound4 compound.in
1. The words on this page...
This is line 2a.
This is line 2b.
3. The words on this page...
4. The words on this page...

The next example uses regular expressions in the addresses. The regular expression in the following instruction (`^.`) matches one character at the beginning of every line that is not empty. The replacement string (between the second and third slashes) contains a backslash escape sequence that represents a TAB character (`\t`) followed by an ampersand (`&`). The ampersand takes on the value of whatever the regular expression matched.

$ sed 's/^./\t&/' new
Line one.

The second line.

The third.

...

This type of substitution is useful for indenting a file to create a left margin. See Appendix A for more information on regular expressions.

You can also use the simpler form `s/^/t/` to add TABs to the beginnings of lines. However, in addition to placing TABs at the beginning of lines with text on them, this instruction places a TAB at the beginning of every empty line—something the preceding command does not do.

You may want to put the preceding `sed` instruction into a shell script so that you do not have to remember it (and retype it) each time you want to indent a file. The `chmod` utility gives you read and execute permission to the `ind` file.

```
$ cat ind

sed 's/^./t/' $*

$ chmod u+rx ind

$ ind new

    Line one.

    The second line.

    The third.

...

Stand-alone script

When you run the preceding shell script, it creates two processes: It calls a shell, which in turn calls `sed`. You can eliminate the overhead associated with the shell process by putting the line `#!/bin/sed` (page 265) at the start of the script, which runs the `sed` utility directly. You need read and execute permission to the file holding the script.

```
$ cat ind2

#!/bin/sed -f

s/^./t/
```

In the following `sed` program, the regular expression (two SPACEs followed by `*\$`) matches one or more SPACEs at the end of a line. This program removes trailing SPACEs at the ends of lines, which is useful for cleaning up files that you created using `vim`.

```
$ cat cleanup

sed 's/ *$//' $*
```

The `cleanup2` script runs the same `sed` command as `cleanup` but stands alone: It calls `sed` directly with no intermediate shell.

```
$ cat cleanup2
#!/bin/sed -f
s/ *$//
```

The next `sed` program makes use of the Hold space to exchange pairs of lines in a file.

```
$ cat s1

h # Copy Pattern space (line just read) to Hold space.
n # Read the next line of input into Pattern space.
p # Output Pattern space.
g # Copy Hold space to Pattern space.
p # Output Pattern space (which now holds the previous line).
```

```
$ sed -nf s1 new

The second line.
Line one.
This is line four.
The third.
This is the sixth sentence.
Five.
```
Eighth and last.

This is line seven.

The commands in the `s1` program process pairs of input lines. This program reads a line and stores it; reads another line and displays it; and then retrieves the stored line and displays it. After processing a pair of lines the program starts over with the next pair of lines.

The next `sed` program adds a blank line after each line in the input file (i.e., it double-spaces a file).

```
$ sed 'G' new
Line one.

The second line.

The third.

This is line four.

$
```

The `G` instruction appends a NEWLINE and the contents of the Hold space to the Pattern space. Unless you put something in the Hold space, it is empty. Thus the `G` instruction copies a NEWLINE to each line of input before `sed` displays the line(s) from the Pattern space.

The `s2` `sed` program reverses the order of the lines in a file just as the `tac` utility does.

```
$ cat s2
2,$G  # On all but the first line, append a NEWLINE and the
       # contents of the Hold space to the Pattern space.
   h   # Copy the Pattern space to the Hold space.
$!d   # Delete all except the last line.

$ sed -f s2 new
```
Eighth and last.

This is line seven.

This is the sixth sentence.

Five.

This is line four.

The third.

The second line.

Line one.

This program includes three commands: 2,$G, h, and $!d. To understand this script it is important to understand how the address of the last command works: The $ is the address of the last line of input and the ! negates the address. The result is an address that selects all except the last line of input. In the same fashion you could replace the first command with 1!G: Select all except the first line for processing; the results would be the same.

Here is what happens as s2 processes the new file:

1. The sed utility reads the first line of input (Line one.) into the Pattern space.
   a. The 2,$G does not process the first line of input because of its address the G instruction starts processing at the second line.
   b. The h copies Line one. from the Pattern space to the Hold space.
   c. The $!d deletes the contents of the Pattern space. Because there is nothing in the Pattern space, sed does not display anything.

2. The sed utility reads the second line of input (The second line.) into the Pattern space.
   a. The 2,$G adds what is in the Hold space (Line one.) to the Pattern space. The Pattern space now has The second line.NEWLINE Line one.
   b. The h copies what is in the Pattern space to the Hold space.
   c. The $!d deletes the second line of input. Because it is deleted, sed does not display it.

3. The sed utility reads the third line of input (The third.) into the Pattern space.
   a. The 2,$G adds what is in the Hold space (The second line.NEWLINE Line one.) to the Pattern space. The Pattern space now has The third.NEWLINE The second line.NEWLINE Line one.
b. The \texttt{h} copies what is in the Pattern space to the Hold space.

c. The \texttt{!d} deletes the contents of the Pattern space. Because there is nothing in the Pattern space, \texttt{sed} does not display anything.

\ldots

8. The \texttt{sed} utility reads the eighth (last) line of input into the Pattern space.

a. The \texttt{2,$G} adds what is in the Hold space to the Pattern space. The Pattern space now has all the lines from \texttt{new} in reverse order.

b. The \texttt{h} copies what is in the Pattern space to the Hold space. This step is not necessary for the last line of input but does not alter the program's output.

c. The \texttt{!d} does not process the last line of input. Because of its address the \texttt{d} instruction does not delete the last line.

d. The \texttt{sed} utility displays the contents of the Pattern space.
Chapter Summary

The sed (stream editor) utility is a batch (noninteractive) editor. It takes its input from files you specify on the command line or from standard input. Unless you redirect the output from sed, it goes to standard output.

A sed program consists of one or more lines with the following syntax:

```
[  
  address  
  [ ,  
  address  
  ] ]  
instruction  
[  
  argument-list  
  ]
```

The addresses are optional. If you omit the address, sed processes all lines of input. The instruction is the editing instruction that modifies the text. The addresses select the line(s) the instruction part of the command operates on. The number and kinds of arguments in the argument-list depend on the instruction.

In addition to basic instructions, sed includes some powerful advanced instructions. One set of these instructions allows sed programs to store data temporarily in a buffer called the Hold space. Other instructions provide unconditional and conditional branching in sed programs.
Exercises

1: Write a `sed` command that copies a file to standard output, removing all lines that begin with the word `Today`.

2: Write a `sed` command that copies only those lines of a file that begin with the word `Today` to standard output.

3: Write a `sed` command that copies a file to standard output, removing all blank lines (lines with no characters on them).

4: Write a `sed` program named `ins` that copies a file to standard output, changing all occurrences of `cat` to `dog` and preceding each modified line with a line that says `following line is modified`.

5: Write a `sed` program named `div` that copies a file to standard output, copies the first five lines to a file named `first`, and copies the rest of the file to a file named `last`.

6: Write a `sed` command that copies a file to standard output, replacing a single SPACE as the first character on a line with a 0 (zero) only if the SPACE is immediately followed by a number (009). For example:

```
abc  → abc
abc  → abc
85c  → 085c
55b  → 55b
000  → 0000
```

7: How can you use `sed` to triple-space (i.e., add two blank lines after each line in) a file?
Command Reference

The following tables list the utilities covered in this part of the book grouped by function and alphabetically within function. Although most of these are true utilities (programs that are separate from the shells), some are built into the shells (shell builtins). The sample utility on page 588 shows the format of the description of each utility in this part of the book.
Utilities That Display and Manipulate Files

aspell  Checks a file for spelling errors\[page 589
bzip2   Compresses or decompresses files\[page 596
cat     Joins and displays files\[page 599
cmp     Compares two files\[page 610
comm    Compares sorted files\[page 612
cp      Copies files\[page 616
cpio    Creates an archive or restores files from an archive\[page 619
cut     Selects characters or fields from input lines\[page 627
dd      Converts and copies a file\[page 633
diff    Displays the differences between two files\[page 638
find    Finds files based on criteria\[page 655
fmt     Formats text very simply\[page 664
gawk    Searches for and processes patterns in a file\[page 527
grep    Searches for a pattern in files\[page 683
gzip    Compresses or decompresses files\[page 688
head    Displays the beginning of a file\[page 691
less    Displays text files, one screen at a time\[page 697
ln      Makes a link to a file\[page 702
lpr     Sends files to printers\[page 705
ls       Displays information about one or more files\[page 708
man     Displays documentation for commands\[page 721
mkdir   Creates a directory\[page 724
mv      Renames or moves a file\[page 732
od      Dumps the contents of a file\[page 737
paste   Joins corresponding lines from files\[page 742
pr      Paginates files for printing\[page 744
rm      Removes a file (deletes a link)\[page 753
rmdir   Removes a directory\[page 755
sed     Edits a file (not interactively)\[page 563
sort    Sorts and/or merges files\[page 762
split   Divides a file into sections\[page 771
strings Displays strings of printable characters\[page 777
tail    Displays the last part (tail) of a file\[page 783
tar     Stores or retrieves files to/from an archive file\[page 786
touch   Changes a file's access and/or modification time\[page 801
uniq    Displays unique lines\[page 812
wc      Displays the number of lines, words, and bytes\[page 816
### Network Utilities

- **ftp**: Transfers files over a network. Page 671
- **rcp**: Copies one or more files to or from a remote system. Page 750
- **rlogin**: Logs in on a remote system. Page 752
- **rsh**: Executes commands on a remote system. Page 756
- **scp**: Securely copies one or more files to or from a remote system. Page 758
- **ssh**: Securely executes commands on a remote system. Page 773
- **telnet**: Connects to a remote system over a network. Page 792
Utilities That Display and Alter Status

- `cd` Changes to another working directory (page 601)
- `chgrp` Changes the group associated with a file (page 603)
- `chmod` Changes the access mode (permissions) of a file (page 604)
- `chown` Changes the owner of a file and/or the group the file is associated with (page 608)
- `date` Displays or sets the system time and date (page 630)
- `df` Displays disk space usage (page 636)
- `du` Displays information on disk usage by file (page 644)
- `file` Displays the classification of a file (page 653)
- `finger` Displays information about users (page 661)
- `kill` Terminates a process by PID (page 693)
- `killall` Terminates a process by name (page 695)
- `nice` Changes the priority of a command (page 734)
- `nohup` Runs a command that keeps running after you log out (page 736)
- `ps` Displays process status (page 746)
- `sleep` Creates a process that sleeps for a specified interval (page 760)
- `stty` Displays or sets terminal parameters (page 778)
- `top` Dynamically displays process status (page 798)
- `umask` Establishes the file-creation permissions mask (page 810)
- `w` Displays information about system users (page 814)
- `which` Shows where in PATH a command is located (page 817)
- `who` Displays information about logged-in users (page 819)
Utilities That Are Programming Tools

- **configure**: Configures source code automatically [page 614]
- **gcc**: Compiles C and C++ programs [page 678]
- **make**: Keeps a set of programs current [page 715]
Miscellaneous Utilities

**at**     Executes commands at a specified time  page 593
**cal**     Displays a calendar  page 598
**crontab** Maintains crontab files  page 624
**echo**   Displays a message  page 647
**expr**    Evaluates an expression  page 649
**fsck**    Checks and repairs a filesystem  page 666
**mkfs**    Creates a filesystem on a device  page 725
**Mtools** Uses DOS-style commands on files and directories  page 728
**tee**     Copies standard input to standard output and one or more files  page 791
**test**    Evaluates an expression  page 794
**TR**      Replaces specified characters  page 804
**tty**     Displays the terminal pathname  page 807
**tune2fs** Changes parameters on an ext2 or ext3 filesystem  page 808
**xargs**   Converts standard input into command lines  page 821
Standard Multiplicative Suffixes

Several utilities allow you to use the suffixes listed in Table V-1 following byte counts. You can precede a multiplicative suffix with a number that is a multiplier. For example, 5K means $5 \times 2^{10}$. The absence of a multiplier indicates that the multiplicative suffix is to be multiplied by 1. The utilities that allow these suffixes are marked as such.

<table>
<thead>

Common Options

Several GNU utilities share the options listed in Table V-2. The utilities that use these options are marked as such.

<table>
<thead>
<tr>
<th>Option</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>A single hyphen appearing in place of a filename indicates that the utility will accept standard input in place of the file.</td>
<td></td>
</tr>
<tr>
<td>A double hyphen marks the end of the options on a command line. You can follow this option with an argument that begins with a hyphen. Without this option the utility assumes that an argument that begins with a hyphen is an option.</td>
<td></td>
</tr>
<tr>
<td>Displays a help message for the utility. Some of these messages are quite long; you can pipe the output through <code>less</code> to display it one screen at a time. For example, you could give the command `ls help</td>
<td>less<code>. Alternatively you can pipe the output through </code>grep<code>if you are looking for specific information. For example, you could give the following command to get information on the</code>-d<code>option to</code>ls<code>: </code>ls help</td>
</tr>
<tr>
<td>Displays version information for the utility.</td>

</table>
The sample Utility

The following description of the sample utility shows the format that is used to describe the utilities in this part of the book. These descriptions are similar to the man page descriptions (pages 30 and 721); however, most users find the descriptions in this book easier to read and understand. These descriptions emphasize the most useful features of the utilities and often leave out the more obscure features. For information about the less commonly used features, refer to the man and info pages or call the utility with the help option, which works with many utilities.

sample: Very brief description of what the utility does

sample [options] arguments

Following the syntax line is a description of the utility. The syntax line shows how to run the utility from the command line. Options and arguments enclosed in brackets ([ ]) are not required. Type words that appear in this italic typeface as is. Words that you must substitute when you type appear in this bold italic typeface. Words listed as arguments to a command identify single arguments (for example, source-file) or groups of similar arguments (for example, directory-list).

Arguments

This section describes the arguments that you can use when you run the utility. The argument itself, as shown in the preceding syntax line, is printed in this bold italic typeface.

Options

This section lists some of the options you can use with the command. Unless otherwise specified, you must precede options with one or two hyphens. Most commands accept a single hyphen before multiple options (page 109). Options in this section are ordered alphabetically by short (single-hyphen) options. If an option has only a long version (two hyphens), it is ordered by its long option. Following are some sample options:

*make-dirs* `d` This option has a long and a short version. You can use either option; they are equivalent.

*delimiter=dchar*

*d dchar*

This option includes an argument. The argument is set in a bold italic typeface in both the heading and the description. You substitute another word (filename, string of characters, or other value) for any arguments you see in this typeface. Type characters that are in bold type (such as the delimiter and d) as is, letter for letter.

*t (table of contents)* This is an example of a simple option preceded by a single hyphen and not followed with any arguments. It has no long version. The table of contents appearing in parentheses at the beginning of the description is a cue, suggestive of what the option letter stands for.

Discussion

This optional section contains a discussion about how to use the utility and any quirks it may have.
Notes

This section contains miscellaneous notes—some important and others merely interesting.

Examples

This section contains examples of how to use the utility. This section is tutorial and is more casual than the preceding sections of the description.

**aspell: Checks a file for spelling errors**

```
aspell check [options] filename
aspell list [options] < filename
aspell config
aspell help
```

The `aspell` utility checks the spelling of words in a document against a standard dictionary. You can use `aspell` interactively: It displays each misspelled word in context, together with a menu that gives you the choice of accepting the word as is, choosing one of `aspell`'s suggested replacements for the word, inserting the word into your personal dictionary, or replacing the word with one you enter. You can also use `aspell` in batch mode so that it reads from standard input and writes to standard output.

**tip: aspell is not like other utilities regarding its input**

Unlike many other utilities, `aspell` does not accept input from standard input when you do not specify a filename on the command line. Instead, the action specifies where `aspell` gets its input.

**Action**

You must choose one and only one `action` when you run `aspell`.

- **check** (-c) Runs `aspell` as an interactive spelling checker. Input comes from a single file named on the command line. Refer to "Discussion" on page 590.
- **config** Displays `aspell`'s configuration, both default and current values. Send the output through a pipe to `less` for easier viewing, or use `grep` to find the option you are looking for (for example, `aspell config | grep backup`).
- **help** (-?) Displays an extensive page of help. Send the output through a pipe to `less` for easier viewing.
- **list** (-l) Runs `aspell` in batch mode (noninteractively) with input coming from standard input and output going to standard output.

**Arguments**

The `filename` is the name of the file you want to check. The `aspell` utility accepts this argument only when you use the `check` (-c) `action`. With the `list` (-l) `action`, input must come from standard input.

**Options**
The `aspell` utility has many options. A few of the more commonly used ones are listed in this section; see the manual for a complete list. Default values of many options are determined when `aspell` is compiled (see the `config action`).

You can specify options on the command line, in value of the `ASPELL_CONF` shell variable, or in your personal configuration file (`~/.aspell.conf`). Superuser can create a global configuration file (`/etc/aspell.conf`). Put one option per line in a configuration file; separate options with a semicolon (:) in `ASPELL_CONF`. Options on the command line override those in `ASPELL_CONF`, which override those in your personal configuration file, which override those in the global configuration file.

There are two types of options in the following list: Boolean and value. The Boolean options turn a feature on (enable the feature) or off (disable the feature). Precede a Boolean option with `dont` to turn it off. For example, `ignore-case` turns the `ignore-case` feature on and `dont-ignore-case` turns it off.

Value options assign a value to a feature. Follow the option with an equal sign and a value for example, `ignore=4`.

For all options in a configuration file or in the `ASPELL_CONF` variable, drop the leading hyphens (`ignore-case` or `dont-ignore-case`).

**caution: aspell options and leading hyphens**

The way you specify options differs depending on whether you are specifying them on the command line, using the `ASPELL_CONF` shell variable, or in a configuration file.

On the command line prefix long options with two hyphens (for example, `ignore-case` or `dont-ignore-case`). In `ASPELL_CONF` and configuration files, drop the leading hyphens (for example, `ignore-case` or `dont-ignore-case`).

- `dont-backup` Does not create a backup file named `filename.bak` (default is `backup` when `action` is `check`).
- `ignore= n` Ignores words with `n` or fewer characters (default is 1).
- `ignore-case` Ignores the case of letters in words being checked (default is `dont-ignore-case`).
- `lang= cc` Specifies the two-letter language code (`cc`). The language code defaults to the value of `LC_MESSAGES` (page 291).
- `mode= mod` Specifies a filter to use. Select `mod` from `url` (default), `none`, `sgml`, and others. The modes work as follows: `url`: skips URLs, hostnames, and email addresses; `none`: turns off all filters; `sgml`: skips SGML, HTML, XHTML, and XML commands.
- `strip-accents` Removes accent marks from all the words in the dictionary before checking words (default is `dont-strip-accents`).

**Discussion**

The `aspell` utility has two basic modes of operation: batch and interactive. You specify batch mode by using the `list` or `l action`. In batch mode `aspell` takes the document you want to check for spelling errors as standard input and sends the list of potentially misspelled words to standard output.

You specify interactive mode by using the `check` or `c action`. In interactive mode `aspell` displays a screen with the potentially misspelled word in context highlighted in the middle and a menu of choices at the bottom. See "Examples" for an illustration. The menu includes various commands (Table V-3) as well as some suggestions of similar, correctly spelled words. You either enter one of the numbers from the menu to select a suggested word to replace the word in question or enter a letter to give a command.
Table V-3. Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPACE</td>
<td>Takes no action and goes on to next the misspelled word.</td>
</tr>
<tr>
<td>n</td>
<td>Replaces the misspelled word with suggested word number n.</td>
</tr>
<tr>
<td>a</td>
<td>Adds the &quot;misspelled&quot; word to your personal dictionary.</td>
</tr>
<tr>
<td>b</td>
<td>Aborts aspell; does not save changes.</td>
</tr>
<tr>
<td>i or I (letter &quot;i&quot;)</td>
<td>Ignores the misspelled word. I (uppercase &quot;I&quot;) ignores all occurrences of this word; i ignores this occurrence only and is the same as SPACE.</td>
</tr>
<tr>
<td>l</td>
<td>Shifts the &quot;misspelled&quot; word to lowercase and adds it to your personal dictionary.</td>
</tr>
<tr>
<td>r or R</td>
<td>Replaces the misspelled word with the word that you enter at the bottom of the screen. R replaces all occurrences of this word; r replaces this occurrence only.</td>
</tr>
<tr>
<td>x</td>
<td>Saves the file as corrected so far and exits from aspell.</td>
</tr>
</tbody>
</table>

Notes

For more information refer to the /usr/share/doc/aspell directory with manuals in the man-html and man-text subdirectories and to the aspell home page located at aspell.sourceforge.net.

The aspell utility is not a foolproof way of finding spelling errors. It also does not check for misused, properly spelled words (such as red instead of read).

Spelling from emacs

You can make it easy to use aspell from emacs by adding the following line to your ~/.emacs file. This line causes emacs' ispell functions to call aspell:

```
(setq-default ispell-program-name "aspell")
```

Spelling from vim

Similarly, you can make it easy to use aspell from vim by adding the following line to your ~/.vimrc file:

```
map ^T :w!<CR>:!aspell check %<CR>:e! %<CR>
```

When you enter this line in ~/.vimrc using vim, enter the ^T as CONTROL-V CONTROL-T (page 159). With this line in ~/.vimrc, CONTROL-T brings up aspell to spell check the file you are editing with vim.

Examples

The following examples use aspell to correct the spelling in the memo.txt file:
Here's a document for teh aspell utilitey
to check. It obviosly needs proofing quiet badly.

The first example uses `aspell` with the `check action` and no options. The appearance of the screen for the first misspelled word, `teh`, is shown. At the bottom of the screen is the menu of commands and suggested words. The numbered words each differ slightly from the misspelled word:

```
$ aspell check memo.txt

Here's a document for teh aspell utilitey
to check. It obviosly needs proofing quiet badly.

============================================================
1)  the                                  6) th
2)  Te                                   7) tea
3) tech                                 8) tee
4) Th                                   9) Ted
5) eh                                   0) tel
i) Ignore                               I) Ignore all
r) Replace                              R) Replace all
a) Add                                  1) Add Lower
b) Abort                                x) Exit
```

?
Enter one of the menu choices in response to the preceding display; `aspell` will do your bidding and move the highlight to the next misspelled word (unless you choose to abort or exit).

The next example uses the `list` action to display a list of misspelled words. The word `quiet` is not in the list—it is not properly used but is properly spelled.

```bash
$ aspell list < memo.txt
teh
aspell
utilitey
obviosly
```

The last example also uses the `list` action. It shows a quick way to check the spelling of a word or two with a single command. The user gives the `aspell list` command and then enters `seperate temperature` into `aspell`’s standard input (the keyboard). After the user enters RETURN and CONTROL-D (to mark the end of file), `aspell` writes the misspelled word to standard output (the screen):

```bash
$ aspell list
seperate temperatureRETURN
CONTROL-D
seperate
```

### at: Executes commands at a specified time

```
at [options] time [date | +increment]
atq
atrm job-list
batch [options] [time]
```

The `at` and `batch` utilities execute commands at a specified time. They accept commands from standard input or, with the `if` option, from a file. Commands are executed in the same environment as the `at` or `batch` command. Unless redirected, standard output and standard error from commands are emailed to the user who ran `at` or `batch`. A `job` is the group of commands that is executed by one call to `at`. The `batch` utility differs from `at` in that it schedules jobs so that they run when the CPU load on the system is low.

The `atq` utility displays a list of `at` jobs you have queued; `atrm` cancels pending `at` jobs.

### Arguments

The `time` is the time of day that `at` runs the job. You can specify the `time` as a one-, two-, or four-digit number. One- and two-digit numbers specify an hour, and four-digit numbers specify an hour and minute. You can also give the time in the form `hh:mm`. The `at` utility assumes a 24-hour clock unless you place `am` or `pm` immediately after the
number, in which case it uses a 12-hour clock. You can also specify time as now, midnight, noon, or teatime (4:00 PM).

The date is the day of the week or day of the month on which you want at to execute the job. When you do not specify a day, at executes the job today if the hour you specify in time is greater than the current hour. If the hour is less than the current hour, at executes the job tomorrow.

You specify a day of the week by spelling it out or abbreviating it to three letters. You can also use the words today and tomorrow. Use the name of a month followed by the number of the day in the month to specify a date. You can follow the month and day number with a year.

The increment is a number followed by one of the following (plural or singular is allowed): minutes, hours, days, or weeks. The at utility adds the increment to time. You cannot specify an increment for a date.

When using atrm, job-list is a list of one or more at job numbers. You can list job numbers by running at with the l option or by using atq.

Options

The l and d options are not for use when you initiate a job with at. You can use them only to determine the status of a job or to cancel a job.

-c job-list (cat) Displays the environment and commands specified by job-list.

-d job-list (delete) Cancels jobs that you previously submitted with at. The job-list argument is a list of one or more at job numbers to cancel. If you do not remember the job number, use the l option or run atq to list your jobs and their numbers. Using this option with at is the same as running atrm.

-f file (file) Specifies that commands come from file instead of standard input. This option is useful for long lists of commands or commands that are executed repeatedly.

-l (list) Displays a list of your at jobs. Using this option with at is the same as running atq.

-m (mail) Sends you email after a job is run, even when nothing is sent to standard output or standard error. When a job generates output, at always emails it to you, regardless of this option.

Notes

The shell saves the environment variables and the working directory at the time you submit an at job so that they are available when at executes commands.

/etc/at.allow and /etc/at.deny

The root user can always use at. The /etc/at.allow and /etc/at.deny files, which should be readable and writable by root only (mode 600), control which ordinary, local users can use at. When /etc/at.deny exists and is empty, all users can use at. When /etc/at.deny does not exist, only users listed in /etc/at.allow can use at. Users listed in /etc/at.deny cannot use at unless they are also listed in /etc/at.allow.

Jobs you submit using at are run by the at daemon (atd). This daemon stores jobs in /var/spool/at and output in /var/spool/at/spool, both of which should be set to mode 700 and owned by the user named daemon.
Examples

You can use any of the following techniques to paginate and print `long_file` tomorrow at 2:00 AM. The first example executes the command directly from the command line; the last two examples use the `pr_tonight` file, which contains the necessary command, and execute it using `at`.

```bash
$ at 2am
at> pr long_file | lpr
at>CONTROL-D<EOT>
job 8 at 2005-08-17 02:00

$ cat pr_tonight
#!/bin/bash
pr long_file | lpr

$ at -f pr_tonight 2am
job 9 at 2005-08-17 02:00

$ at 2am < pr_tonight
job 10 at 2005-08-17 02:00

If you execute commands directly from the command line, you must signal the end of the commands by pressing CONTROL-D at the beginning of a line. After you press CONTROL-D, `at` displays a line that begins with `job` followed by the job number and the time `at` will execute the job.

If you run `atq` after the preceding commands, it displays a list of jobs in its queue:

```bash
$ atq
8 2005-08-17 02:00 a
9 2005-08-17 02:00 a
10 2005-08-17 02:00 a
```

The following command removes job number 9 from the queue:
$ atrm 9
$ atq
8       2005-08-17 02:00 a
10      2005-08-17 02:00 a

The next example executes **cmdfile** at 3:30 PM (1530 hours) one week from today:

$ at -f cmdfile 1530 +1 week

job 12 at 2005-08-23 15:30

Next **at** executes a job at 7 PM on Thursday. This job uses **find** to create an intermediate file, redirects the output sent to standard error, and prints the file.

$ at 7pm Thursday

at> find / -name "core" -print >report.out 2>report.err
at> lpr report.out
at>CONTROL-D<EOT>

job 13 at 2005-08-18 19:00

The final example shows some of the output generated by the **c** option when **at** is queried about the preceding job. Most of the lines show the environment; only the last few lines execute the **commands**:

$ at -c 13
#!/bin/sh

# atrun uid=500 gid=500
# mail     mark 0
umask 2
PATH=/usr/kerberos/bin:/usr/local/bin:/bin:/usr/bin:/usr/X11R6/bin:.
export PATH
PWD=/home/mark/book.examples/99/cp; export PWD
EXINIT=set \ ai \ aw; export EXINIT
LANG=C; export LANG

PS1=\$ ; export PS1

... 

cd /home/mark/book\examples/99/cp || {
    echo 'Execution directory inaccessible' >&2
    exit 1
}

find / -name "core" -print >report.out 2>report.err

lpr report.out

bzip2: Compresses or decompresses files

bzip2 [options] [file-list]
bunzip2 [options] [file-list]
bzcat [options] [file-list]
bzip2recover [file]

The bzip2 utility compresses files; bunzip2 restores files compressed with bzip2; bzcat displays files compressed with bzip2.

Arguments

The file-list is a list of one or more files (no directories) that are to be compressed or decompressed. If file-list is empty or if the special option is present, bzip2 reads from standard input. The stdout option causes bzip2 to write to standard output.

Options

Accepts the common options described on page 587.

stdout  Writes the results of compression or decompression to standard output.

decompress  Decompresses a file compressed with bzip2. This option with bzip2 is equivalent to the bunzip2 command.

fast or best  Sets the block size when compressing a file. The n is a digit from 1 to 9, where 1 (fast) generates a block size of 100 kilobytes and 9 (best) generates a block size of 900 kilobytes. The default level is 9. The options fast and best are provided for compatibility with gzip and do not necessarily yield the fastest or best compression.

force  Forces compression even if a file already exists, has multiple links, or comes directly from a terminal. The option has a similar effect with bunzip2.
**keep**

Does not delete input files while compressing or decompressing them.

**quiet**

Suppresses warning messages; does display critical messages.

**test**

Verifies the integrity of a compressed file. Displays nothing if the file is OK.

**verbose**

For each file being compressed displays the name of the file, the compression ratio, the percentage of space saved, and the sizes of the decompressed and compressed files.

**Discussion**

The **bzip2** and **bunzip2** utilities work similarly to **gzip** and **gunzip**; see the discussion of **gzip** (page 689) for more information. Normally **bzip2** does not overwrite a file; you must use **force** to overwrite a file during compression or decompression.

**Notes**

The **bzip2** home page is sources.redhat.com/bzip2.

The **bzip2** utility does a better job of compressing files than **gzip**.

Use the **bzip2** modifier with **tar** (page 788) to compress archive files with **bzip2**.

**bzcat file-list**

Works like **cat** except that it uses **bunzip2** to decompress **file-list** as it copies files to standard output.

**bzip2recover**

Attempts to recover a damaged file that was compressed with **bzip2**.

**Examples**

In the following example, **bzip2** compresses a file and gives the resulting file the same name with a .bz2 filename extension. The **v** option displays statistics about the compression.

```
$ ls -l
total 728
-rw-r--r--  1 sam sam 737414 Feb 20 19:05 bigfile
$ bzip2 -v bigfile
  bigfile: 3.926:1, 2.037 bits-byte, 74.53% saved, 737414 in, 187806 out
$ ls -l
```
Next `touch` creates a file with the same name as the original file; `bunzip2` refuses to overwrite the file in the process of decompressing `bigfile.bz2`. The `--force` option enables `bunzip2` to overwrite the file.

```
$ touch bigfile
$ bunzip2 bigfile.bz2
bunzip2: Output file bigfile already exists.
$ bunzip2 --force bigfile.bz2
$ ls -l
```

```
total 728
-rw-r--r--  1 sam  sam  737414 Feb 20 19:05 bigfile
```

`cal`: Displays a calendar

`cal [options] [[month] year]`

The `cal` utility displays a calendar for a month or a year.

**Arguments**

The arguments specify the month and year for which `cal` displays a calendar. The `month` is a decimal integer from 1 to 12 and the `year` is a decimal integer. Without any arguments, `cal` displays a calendar for the current month. When you specify a single argument, it is taken to be the year.

**Options**

- `j` *(Julian)* Displays a Julian calendar—a calendar that numbers the days consecutively from January 1 (1) through December 31 (365 or 366).
- `m` *(Monday)* Makes Monday the first day of the week. Without this option, Sunday is the first day of the week.
- `y` *(year)* Displays a calendar for the current year.
- `3` *(three months)* Displays the previous, current, and next months.

**Notes**

Do not abbreviate the year. The year `05` is not the same as `2005`. 
Examples

The following command displays a calendar for August 2007:

$ cal 8 2007

     August 2007
 Su Mo Tu We Th Fr Sa
     1  2  3  4
     5  6  7  8  9 10 11
    12 13 14 15 16 17 18
    19 20 21 22 23 24 25
    26 27 28 29 30 31

Next is a Julian calendar for 1949 with Monday as the first day of the week:

$ cal -jm 1949

     1949
                January                      February
Mon Tue Wed Thu Fri Sat Sun     Mon Tue Wed Thu Fri Sat Sun
     1  2            32  33  34  35  36  37
     3  4  5  6  7  8  9  38  39  40  41  42  43  44
    10 11 12 13 14 15 16  45  46  47  48  49  50  51
    17 18 19 20 21 22 23  52  53  54  55  56  57  58
    24 25 26 27 28 29 30  59
    31 ...

cat: Joins and displays files

cat [options] [file-list]

The cat utility copies files to standard output. You can use cat to display the contents of one or more text files on the screen.
Arguments

The **file-list** is a list of the pathnames of one or more files that **cat** processes. If you do not specify an argument or if you specify a hyphen (\-) in place of a filename, **cat** reads from standard input.

Options

Accepts the **common options** described on page 587.

- **\&show-all** \&A Same as \&vET.

- **\&number-nonblank**
  - \&b Numbers all lines that are not blank as they are written to standard output.
  - \&e (end) Same as \&vE.

- **\&show-ends** \&E Marks the ends of lines with dollar signs.

- **\&number** \&n (number) Numbers all lines as they are written to standard output.

- **\&squeeze-blank** \&s Removes extra blank lines so there are never two or more blank lines in a row.
  - \&t (tab) Same as \&vT.

- **\&show-tabs** \&T Marks each TAB with ^I.

- **\&show-nonprinting**
  - \&v Displays CONTROL characters with the caret notation (^M) and displays characters that have the high bit set (META characters) with the M- notation. This option does not convert TABs and LINEFEEDs. Use **\&show-tabs** if you want to display TABs as ^I. LINEFEEDs cannot be displayed as anything but themselves; otherwise, the line would be too long.

Notes

See page 115 for a discussion of **cat**, standard input, and standard output.

Use the **od** utility (page 737) to display the contents of a file that does not contain text (for example, an executable program file).

Use the **tac** utility to display lines of a text file in reverse order. See the **tac** info page for more information.

The name **cat** is derived from one of the functions of this utility, **catenate**, which means to join together sequentially, or end to end.

**caution: Set noclobber to avoid overwriting a file**

Despite **cat**'s warning message, the shell destroys the input file (letter) before invoking **cat** in the following example:
$ cat memo letter > letter

cat: letter: input file is output file

You can prevent overwriting a file in this situation by setting the noclobber variable (pages 119 and 367).

Examples

The following command displays the contents of the memo text file on the terminal:

$ cat memo

...

The next example catenates three text files and redirects the output to the all file:

$ cat page1 letter memo > all

You can use cat to create short text files without using an editor. Enter the following command line, type (or paste) the text you want in the file, and press CONTROL-D on a line by itself:

$ cat > new_file

...

(text)

...

CONTROL-D

In this case cat takes input from standard input (the keyboard) and the shell redirects standard output (a copy of the input) to the file you specify. The CONTROL-D signals the EOF (end of file) and causes cat to return control to the shell (page 116).

In the next example, a pipe sends the output from who to standard input of cat. The shell redirects cat's output to the file named output that, after the commands have finished executing, contains the contents of the header file, the output of who, and footer. The hyphen on the command line causes cat to read standard input after reading header and before reading footer.

$ who | cat header - footer > output

cd: Changes to another working directory
cd [options] [directory]

The cd builtin makes directory the working directory.

Arguments

The directory is the pathname of the directory you want to be the new working directory. Without an argument, cd makes your home directory the working directory. Using a hyphen in place of directory changes to the previous working directory.

Notes

The cd command is a bash and tcsh builtin.

See page 82 for a discussion of cd.

Without an argument, cd makes your home directory the working directory; it uses the value of the HOME (bash; page 283) or home (tcsh, page 362) variable for this purpose.

With an argument of a hyphen, cd makes the previous working directory the working directory. It uses the value of the OLDPWD (bash) or owd (tcsh) variable for this purpose.

The CDPATH (bash; page 289) or cdpath (tcsh; page 362) variable contains a colon-separated list of directories that cd searches. Within the list a null directory name (::) or a period (::) represents the working directory. If CDPATH or cdpath is not set, cd searches only the working directory for directory. If this variable is set and directory is not an absolute pathname (does not begin with a slash), cd searches the directories in the list; if the search fails, cd searches the working directory. See page 289 for a discussion of CDPATH.

Examples

The following cd command makes Alex's home directory his working directory. The pwd builtin verifies the change:

$ pwd
/home/alex/literature

$ cd

$ pwd
/home/alex

The next command makes the /home/alex/literature directory the working directory:

$ cd /home/alex/literature
$ pwd

/home/alex/literature

Next the cd utility makes a subdirectory of the working directory the new working directory:

$ cd memos

$ pwd

/home/alex/literature/memos

Finally cd uses the .. reference to the parent of the working directory to make the parent the new working directory:

$ cd ..

$ pwd

/home/alex/literature

chgrp: Changes the group associated with a file

chgrp [options] group file-list
chgrp [options] --reference=rfile file-list

The chgrp utility changes the group associated with one or more files.

Arguments

The group is the name or numeric group ID of the new group. The file-list is a list of the pathnames of the files whose group association is to be changed. The rfile is the pathname of a file whose group is to become the new group associated with file-list.

Options

- changes  
  Displays a message for each file whose group is changed.
- dereference
  Changes the group IDs of the files symbolic links point to, not the symbolic links themselves. The default is no-dereference.
- quiet or silent
  Prevents the display of warning messages about files whose permissions prevent you from changing their group IDs.

- no-dereference
Changes the group IDs of symbolic links, not the files that the links point to (default).

Recursively descends a directory specified in file-list and changes the group ID on all files in the directory hierarchy.

Changes the group of the files in file-list to that of rfile.

Displays for each file a message saying whether its group was retained or changed.

Notes

Only the owner of a file or root can change the group association of a file. Also, unless you are root, you must belong to the specified group to change the group ID of a file to that group.

See page 608 for information on how chown can change the group associated with, as well as the owner of, a file.

Examples

The following command changes the group that the manuals file is associated with; the new group is pubs.

$ chgrp pubs manuals

chmod: Changes the access mode (permissions) of a file

chmod [options] who operator permission file-list (symbolic)
chmod [options] mode file-list (absolute)
chmod [options] reference=rfile file-list (referential)

The chmod utility changes the ways in which a file can be accessed by the owner of the file, the group to which the file belongs, and/or all other users. Only the owner of a file or Superuser can change the access mode, or permissions, of a file. You can specify the new access mode absolutely, symbolically, or referentially.

Arguments

Arguments specify which files are to have their modes changed in what ways.

Symbolic

You can specify multiple sets of symbolic modes (who operator permission) by separating each set from the next with a comma.

The chmod utility changes the access permission for the class of users specified by who. The class of users is designated by one or more of the letters specified in the who column of Table V-4.
Table V-4. Symbolic mode user class specification

<table>
<thead>
<tr>
<th>who</th>
<th>User class</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>u</td>
<td>User</td>
<td>Owner of the file</td>
</tr>
<tr>
<td>g</td>
<td>Group</td>
<td>Group to which the owner belongs</td>
</tr>
<tr>
<td>o</td>
<td>Other</td>
<td>All other users</td>
</tr>
<tr>
<td>a</td>
<td>All</td>
<td>Can be used in place of ugo</td>
</tr>
</tbody>
</table>

Table V-5 lists the symbolic mode operators.

Table V-5. Symbolic mode operators

<table>
<thead>
<tr>
<th>operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Adds permission for the specified user class</td>
</tr>
<tr>
<td>−</td>
<td>Removes permission for the specified user class</td>
</tr>
<tr>
<td>=</td>
<td>Sets permission for the specified user class; resets all other permissions for that user class</td>
</tr>
</tbody>
</table>

The access permission is specified by one or more of the letters listed in Table V-6.

Table V-6. Symbolic mode permissions

<table>
<thead>
<tr>
<th>permission</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>r</td>
<td>Sets read permission</td>
</tr>
<tr>
<td>w</td>
<td>Sets write permission</td>
</tr>
<tr>
<td>x</td>
<td>Sets execute permission</td>
</tr>
<tr>
<td>s</td>
<td>Sets user ID or group ID (depending on the who argument) to that of the owner of the file while the file is being executed (For more information see page 94.)</td>
</tr>
<tr>
<td>t</td>
<td>Sets the sticky bit (Only Superuser can set the sticky bit, and it can be used only with u; see page 903.)</td>
</tr>
<tr>
<td>X</td>
<td>Makes the file executable only if it is a directory or if another user class has execute permission</td>
</tr>
<tr>
<td>u</td>
<td>Sets specified permissions to those of the owner</td>
</tr>
<tr>
<td>g</td>
<td>Sets specified permissions to those of the group</td>
</tr>
<tr>
<td>o</td>
<td>Sets specified permissions to those of others</td>
</tr>
</tbody>
</table>

Absolute

You can use an octal number to specify the access mode. Construct the number by ORing the appropriate values from Table V-7. To OR two octal numbers from this table, just add them. (Refer to Table V-8 for examples.)

Table V-7. Absolute mode specifications

<table>
<thead>
<tr>
<th>mode</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>4000</td>
<td>Sets user ID when the program is executed (page 94)</td>
</tr>
<tr>
<td>2000</td>
<td>Sets group ID when the program is executed (page 94)</td>
</tr>
<tr>
<td>1000</td>
<td>Sticky bit (page 903)</td>
</tr>
<tr>
<td>0400</td>
<td>Owner can read the file</td>
</tr>
</tbody>
</table>
The following examples show how to use the `chmod` utility to change the permissions of the file named `temp`. The
The following examples show how to use the `chmod` utility to change the permissions of the file named `temp`. The initial access mode of `temp` is shown by `ls` (see "Discussion" on page 710 for information about the `ls` display):

```
$ ls -l temp
-rw-rw-r-- 1 alex pubs 57 Jul 12 16:47 temp
```

When you do not follow an equal sign with a permission, `chmod` removes all permissions for the specified user class. The following command removes all access permissions for the group and all other users so that only the owner has access to the file:

```
$ chmod go= temp
$ ls -l temp
-rw------- 1 alex pubs 57 Jul 12 16:47 temp
```

The next command changes the access modes for all users (owner, group, and others) to read and write. Now anyone can read from or write to the file.

```
$ chmod a=rw temp
$ ls -l temp
-rw-rw-rw- 1 alex pubs 57 Jul 12 16:47 temp
```

Using an absolute argument, `a=rw` becomes 666. The next command performs the same function as the previous one:

```
$ chmod 666 temp
```

The next command removes write access permission for other users. As a result members of the `pubs` group can still read from and write to the file, but other users can only read from the file:

```
$ chmod o-w temp
$ ls -l temp
-rw-rw-r-- 1 alex pubs 57 Jul 12 16:47 temp
```

The following command yields the same result, using an absolute argument:

```
$ chmod 664 temp
```

The next command adds execute access permission for all users:
$ chmod a+x temp

$ ls -l temp
-rwxrwxr-x 1 alex pubs 57 Jul 12 16:47 temp

If `temp` is a shell script or other executable file, all users can now execute it. (You need read and execute access to execute a shell script but only execute access to execute a binary file.) The absolute command that yields the same result is

$ chmod 775 temp

The final command uses symbolic arguments to achieve the same result as the preceding one. It sets permissions to read, write, and execute for the owner, and to read and write for the group and other users. A comma separates the sets of symbolic modes.

$ chmod u=rwx,go=rw temp

chown: Changes the owner of a file and/or the group the file is associated with

```
chown [options] owner file-list
chown [options] owner:group file-list
chown [options] owner: file-list
chown [options] :group file-list
chown [options] ::reference=rfile file-list
```

The `chown` utility changes the owner of a file and/or the group the file is associated with. Only `root` can change the owner of a file. Only `root` or the owner of a file who belongs to the new group can change the group a file is associated with.

Arguments

The `owner` is the username or numeric user ID of the new owner. The `file-list` is a list of the pathnames of the files whose ownership and/or group association you want to change. The `group` is the group name or numeric group ID of the new group that the file is associated with. Table V-9 shows the ways you can specify the new `owner` and/or `group`.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>owner</td>
<td>The new owner of <code>file-list</code>; the group is not changed</td>
</tr>
<tr>
<td>owner:group</td>
<td>The new owner and new group association of <code>file-list</code></td>
</tr>
<tr>
<td>owner:</td>
<td>The new owner of <code>file-list</code>; the group association is changed to that of the new owner's login group</td>
</tr>
<tr>
<td>:group</td>
<td>The new group associated with <code>file-list</code>; the owner is not changed</td>
</tr>
</tbody>
</table>
Options

Accepts the common options described on page 587.

- **changes**  
  Displays a message for each file whose ownership/group is changed.

- **dereference**  
  Changes the ownership/group of the files symbolic links point to, not the symbolic links themselves. The default is **no-dereference**.

- **quiet** or **silent**  
  Prevents `chown` from displaying error messages when it is unable to change the ownership/group of a file.

- **no-dereference**
  
  - **h**  
    Changes the ownership/group of symbolic links, not the files that the links point to (default).
  
- **recursive**  
  - **R**  
    When you include directories in the `file-list`, this option descends the directory hierarchy, setting the specified ownership/group for all files encountered.

- **reference=rfile**
  
  Changes the ownership and group association of the files in the `file-list` to that of `rfile`.

- **verbose**  
  - **v**  
    Displays for each file a message saying whether its ownership/group was retained or changed.

Notes

The `chown` utility clears setuid and setgid bits when it changes the owner of a file.

Examples

The following command changes the owner of the `chapter1` file in the `manuals` directory. The new owner is Jenny:

```
# chown jenny manuals/chapter1
```

The following command makes Alex the owner of, and Alex's login group the group associated with, all files in the `/home/alex/literature` directory and in all its subdirectories:

```
# chown --recursive alex: /home/alex/literature
```

The next command changes the ownership of the files in `literature` to `alex` and the group associated with these files to `pubs`:

```
# chown alex:pubs /home/alex/literature/*
```

The final example changes the group association of the files in `manuals` to `pubs` without altering their ownership. The owner of the files, who is executing this command, must belong to the `pubs` group.
$ chown :pubs manuals/*

cmp: Compares two files

cmp [options] file1 [file2 [skip1 [skip2]]]

The `cmp` utility displays the differences between two files on a byte-by-byte basis. If the files are the same, `cmp` is silent. If the files differ, `cmp` displays the byte and line number of the first difference.

Arguments

The `file1` and `file2` are pathnames of the files that `cmp` compares. If `file2` is omitted, `cmp` uses standard input instead. Using a hyphen (\( - \)) in place of `file1` or `file2` causes `cmp` to read standard input instead of that file.

The `skip1` and `skip2` are decimal numbers indicating the number of bytes to skip in each file before beginning the comparison.

Options

- **printbytes** \( b \) Displays more information, including filenames, byte and line number, as well as octal and ASCII values of the first differing byte.

- **ignoreinitial=n**

  \( i \ n \)

  Skips the first \( n \) bytes in both files before beginning the comparison.

- **verbose** \( v \)

  (lowercase "v") Instead of stopping at the first byte that differs, continues comparing the two files and displays both the location and the value of each byte that differs. Locations are displayed as decimal byte count offsets from the beginning of the files; byte values are displayed in octal. The comparison terminates when an EOF is encountered on either file.

- **silent** or **quite** \( s \)

  Suppresses output from `cmp`; only sets the exit status (see "Notes").

Notes

Byte and line numbering start at 1.

The `cmp` utility does not display a message if the files are identical; it only sets the exit status. This utility returns an exit status of 0 if the files are the same and 1 if they are different. An exit status greater than 1 means an error occurred.

When you use `skip1` (and `skip2`), the offset values `cmp` displays are based on the byte where the comparison began. You can use the standard multiplicative suffixes after `skip1` and `skip2`; see Table V-1 on page 586.
Unlike **diff** (page 638), **cmp** works with binary as well as ASCII files.

**Examples**

The examples use the files **a** and **b** shown below. These files have two differences. The first difference is that the word **lazy** in file **a** is replaced by **lasy** in file **b**. The second difference is more subtle: A TAB character appears just before the NEWLINE character in file **b**.

```
$ cat a
The quick brown fox jumped over the lazy dog.
$ cat b
The quick brown fox jumped over the lasy dog.TAB
```

The first example uses **cmp** without any options to compare the two files. The **cmp** utility reports that the files are different and identifies the offset from the start of the files where the first difference is found:

```
$ cmp a b
a b differ: char 39, line 1
```

You can display the values of the bytes at that location by adding the **printchars** option:

```
$ cmp --print-bytes a b
a b differ: char 39, line 1 is 172 z 163 s
```

The **l** option displays all bytes that differ between the two files. Because this option creates a lot of output if the files have many differences, you may want to redirect the output to a file. The following example shows the two differences between files **a** and **b**. The **lb** option displays the values for the bytes as well. Where file **a** has a CONTROL\J (NEWLINE), file **b** has a CONTROL\I (TAB). The message saying that it has reached the end of file on file **a** indicates that file **b** is longer than file **a**.

```
$ cmp -lb a b
39 172 z 163 s
46  12 ^J  11 ^I
cmp: EOF on a
```

In the next example, the **ignoreinitial** option is used to skip over the first difference in the files. The **cmp** utility now reports on the second difference. The difference is put at character 7, which is the 46th character in the original

```
```
file b (7 characters past the ignored 39 characters).

```
$ cmp --ignore-initial=39 a b
a b differ: char 7, line 1
```

You can use `skip1` and `skip2` in place of the `ignore-initial` option used in the preceding example:

```
$ cmp a b 39 39
a b differ: char 7, line 1
```

**comm: Compares sorted files**

```
comm [options] file1 file2
```

The `comm` utility displays a line-by-line comparison of two sorted files. The first of the three columns it displays lists the lines found only in `file1`, the second column lists the lines found only in `file2`, and the third lists the lines common to both files.

**Arguments**

The `file1` and `file2` are pathnames of the files that `comm` compares. Using a hyphen (`-`) in place of `file1` or `file2` causes `comm` to read standard input instead of that file.

**Options**

You can combine the options.

- `1` Does not display column 1 (does not display lines found only in `file1`).
- `2` Does not display column 2 (does not display lines found only in `file2`).
- `3` Does not display column 3 (does not display lines found in both files).

**Notes**

If the files have not been sorted, `comm` will not work properly.

Lines in the second column are preceded by one TAB, and those in the third column are preceded by two TABs.

The exit status indicates whether `comm` completed normally (0) or abnormally (not 0).

**Examples**
The following examples use two files, c and d, in the working directory. As with all input to `comm`, the files have already been sorted:

```bash
$ cat c
 bbbbbb
cccccc
dddddd
eeeeee
 fffffd

$ cat d
 aaaaaa
dddddd
eeeeee
gggggg
 hhhhh
```

Refer to `sort` on page 762 for information on sorting files.

The following example calls `comm` without any options, so it displays three columns. The first column lists those lines found only in file c, the second column lists those found in d, and the third lists the lines found in both c and d:

```bash
$ comm c d

 aaaaaa
 bbbbbb
 cccccc

dddddd
eeeee

 fffffd
 gggggg
 hhhhh
```
The next example shows the use of options to prevent `comm` from displaying columns 1 and 2. The result is column 3, a list of the lines common to files `c` and `d`:

```
$ comm -12 c d

ddddd
eeeeee
```

**configure: Configures source code automatically**

`./configure` options

The `configure` script is part of the GNU Configure and Build System. Software developers who supply source code for their products face the problem of making it easy for relatively naive users to build and install their software package on a wide variety of machine architectures, operating systems, and system software. Toward this end many software developers supply a shell script named `configure` with their source code.

When you run `configure`, it determines the capabilities of the local system. The data collected by `configure` is used to build the makefiles with which `make` (page 715) builds the executables and libraries. You can adjust the behavior of `configure` by specifying command line options and environment variables.

**Options**

- **disable-feature**
  Works in the same manner as `enable-feature` except that it disables support for `feature`.

- **enable-feature**
  Replace `feature` with the name of a feature that can be supported by the software being configured. For example, configuring the Z Shell source code with the command `configure --enable-zsh-mem` configures the source code to use the special memory allocation routines provided with `zsh` instead of using the system memory allocation routines. Check the README file supplied with the software distribution to see the choices available for `feature`.

- **help**
  Displays a detailed list of all options available for use with `configure`. The contents of this list depends on the software distribution being configured.

- **prefix=directory**
  By default `configure` builds makefiles that install software in the `/usr/local` directory (when you give the command `make install`). To install into a different directory, replace `directory` with the pathname of the directory you want to install the software in.

- **with-package**
  Replace `package` with the name of an optional package that can be included with the software you are configuring. For example, if you configure the source code for the Windows emulator `wine` with the command `configure --with-dll`, the source code is configured to build a shared library of
Windows emulation support. Check the README file supplied with the software distribution to see the choices available for package. Also, configure --help usually displays the choices available for package.

Discussion

The GNU Configure and Build System allows software developers to distribute software that can configure itself to be built on a variety of systems. This system builds a shell script named configure, which prepares the software distribution to be built and installed on a local system. The configure script searches the local system to find the various dependencies for the software distribution and constructs the appropriate makefiles. Once you have run configure, you can build the software with a make command and install the software with a make install command.

The configure script determines which C compiler to use (usually gcc) and specifies a set of flags to pass to that compiler. You can set the environment variables CC and CFLAGS to override these values with your own choices. (See the "Examples" section.)

Notes

Each package that uses the GNU autoconfiguration utility provides its own custom copy of configure, which the software developer created using the GNU autoconf utility. Read the README and INSTALL files that are provided with the package you are installing to obtain detailed information about the available options.

The configure scripts are self-contained and run correctly on a wide variety of systems. You do not need any special system resources to use configure.

Examples

The simplest way to call configure is to cd to the base directory for the software distribution you want to configure and then run the following command:

```
$ ./configure
```

The ./ is prepended to the command name to ensure that you are running the configure script that was supplied with the software distribution. To cause configure to build makefiles that pass the flags -Wall and -O2 to gcc, use the following command from bash:

```
$ CFLAGS="-Wall -O2" ./configure
```

If you are using tcsh, use the following command:

```
tcsh $ env CFLAGS="-Wall -O2" ./configure
```

cp: Copies files
The **cp** utility copies one or more files. It can either make a copy of a single file (first format) or it can copy one or more files to a directory (second format). With the **recursive** option, **cp** can copy directories.

**Arguments**

The **source-file** is the pathname of the file that **cp** makes a copy of. The **destination-file** is the pathname that **cp** assigns to the resulting copy of the file.

The **source-file-list** is a list of one or more pathnames of files that **cp** makes copies of. The **destination-directory** is the pathname of the directory in which **cp** places the copied files. With this format, **cp** gives each of the copied files the same simple filename as its **source-file**.

The **recursive** option enables **cp** to copy directories recursively from the **source-file-list** into the **destination-directory**.

**Options**

Accepts the **common options** described on page 587.

- **archive** a Attempts to preserve as many attributes of **source-file** as possible. Same as dpPR.
- **backup** b If copying a file would remove or overwrite an existing file, this option makes a backup copy of the file that would be overwritten. The backup copy has the same name as the **destination-file** with a tilde (~) appended to it. When you use both **backup** and **force**, **cp** makes a backup copy when you try to copy a file over itself.
- **d** Copies symbolic links, not the files that links point to. Also preserves hard links in **destination-file** s that exist between corresponding **source-file** s. This option is equivalent to **no-dereference** and **preserve=links**.
- **force** f When the **destination-file** exists and cannot be opened for writing, this option causes **cp** to try to remove **destination-file** before copying **source-file**. This option is useful when the user copying a file does not have write permission to an existing **destination-file** but has write permission to the directory containing the **destination-file**. See also **backup**.
- **interactive** i Prompts you whenever **cp** would overwrite a file. If you respond with a string that starts with y or Y, **cp** continues. If you enter anything else, **cp** does not copy the file.
- **dereference** L Copies the file that a symbolic link points to. See **no-dereference**.
- **preserve** p Creates a **destination-file** with the same owner, group, permissions, access date, and modification date as the **source-file**.

**no-dereference**

- **P** Copies symbolic links, not the files that the links point to. Without the **R**, **r**, or **recursive** option, the default behavior is to dereference links (copy the files that links point to, not the links). With one of these options, **cp** does not dereference symbolic links (it copies the links, not the files that the links point to).
- **parents** Copies a relative pathname to a directory, creating directories as needed. (See "Examples.")
When recursively copying directories, attempts to preserve hard links in destination-files that exist between corresponding source-files.

*preserve=links*

Recursively copies directory hierarchies including ordinary files. The no-dereference option is implied.

*recursive R or r*

Copies only when the destination-file does not exist or when it is older than the source-file.

*update u*

Displays the name of each file as cp copies it.

*verbose v*

Notes

If the destination-file exists before you execute cp, cp overwrites the file, destroying the contents but leaving the access privileges, owner, and group associated with the file as they were.

If the destination-file does not exist, cp uses the access privileges of the source-file. The user who copies the file becomes the owner of the destination-file and the user's group becomes the group associated with the destination-file.

With the p option, cp attempts to set the owner, group, permissions, access date, and modification date to match those of the source-file.

Unlike ln (page 702), the destination-file that cp creates is independent of its source-file.

Examples

The first command makes a copy of the file letter in the working directory. The name of the copy is letter.sav.

$ cp letter letter.sav

The next command copies all files with filenames ending in .c into the archives directory, which is a subdirectory of the working directory. Each copied file retains its simple filename but has a new absolute pathname. Because of the preserve option, the copied files in archives have the same owner, group, permissions, access date, and modification date as the source files.

$ cp --preserve *.c archives

The next example copies memo from /home/jenny to the working directory:

$ cp /home/jenny/memo .

The next example uses the parents option to copy the file memo/thursday/max to the dir directory as dir/memo/thursday/max. The find utility shows the newly created directory hierarchy.
$ cp --parents memo/thursday/max dir
$ find dir

dir

dir/memo

dir/memo/thursday

dir/memo/thursday/max

The following command copies the files named memo and letter into another directory. The copies have the same simple filenames as the source files (memo and letter) but have different absolute pathnames. The absolute pathnames of the copied files are /home/jenny/memo and /home/jenny/letter.

$ cp memo letter /home/jenny

The final command demonstrates one use of the \texttt{--force} option. Alex owns the working directory and tries unsuccessfully to copy one onto a file (me) that he does not have write permission for. Because he has write permission to the directory that holds me, Alex can remove the file but not write to it. The \texttt{--force} option unlinks, or removes, me and then copies one to the new file named me.

$ ls -ld

$ ls -l

-rw-r--r-- 1 root root 3555 Oct 21 22:54 me

-rw-rw-r-- 1 alex alex 1222 Oct 21 22:55 one

$ cp one me

cp: cannot create regular file 'me': Permission denied

$ cp --force one me

$ ls -l

-rw-r--r-- 1 alex alex 1222 Oct 21 22:58 me

-rw-rw-r-- 1 alex alex 1222 Oct 21 22:55 one

If Alex had used the \texttt{--backup} option in addition to \texttt{--force}, \texttt{cp} would have created a backup of me named me~. Refer to "Directory Access Permissions" on page 94 for more information.

cpio: Creates an archive or restores files from an archive
The **cpio** utility has three modes of operation: Create mode places multiple files into a single archive file, extract mode restores files from an archive, and pass-through mode copies a directory hierarchy to another location. The archive file used by **cpio** may be saved on disk, tape, other removable media, or a remote system.

Create mode reads a list of ordinary or directory filenames from standard input and writes the resulting archive file to standard output. You can use this mode to create an archive. Extract mode reads the name of an archive from standard input and extracts files from that archive. You can decide to restore all the files from the archive or only those whose names match specific **patterns**. Pass-through mode reads ordinary or directory filenames from standard input and copies the files to another location on the disk.

**Arguments**

By default **cpio** in extract mode extracts all files found in the archive. You can choose to extract files selectively by supplying one or more **patterns**. If the name of a file in the archive matches one of the **patterns**, that file is extracted; otherwise, it is ignored. The **cpio patterns** are similar to shell wildcards (page 127) except that **patterns** match slashes (/) and a leading period (.) in a filename.

In pass-through mode you must give the name of the target **directory** as an argument to **cpio**.

**Options**

**Major Options**

Three options determine the mode in which **cpio** operates. You must include exactly one of these options whenever you use **cpio**.

- **extract**
  
  Reads the archive from standard input and extracts files. Without any **patterns** on the command line, **cpio** extracts all the files from the archive. With **patterns** specified, **cpio** extracts only files with names the **patterns** match. The following example extracts from the SCSI tape at `/dev/st0` only those files whose names end in `.c`:

  ```
  $ cpio -i *.c < /dev/st0
  ```

  The backslash prevents the shell from expanding the `*` before it passes the argument to **cpio**.

- **create**
  
  Constructs an archive from the files named on standard input. These files may be ordinary or directory files, and each must appear on a separate line. The archive is written to standard output as it is built. The **find** utility frequently generates the filenames that **cpio** uses. The following command builds an archive of the entire local system and writes it to the SCSI tape at `/dev/st0`:

  ```
  $ find / -depth -print | cpio -o >/dev/st0
  ```
The `depth` option causes `find` to search for files in a depth-first search, reducing the likelihood of permissions problems when you restore the files from the archive. See the discussion of this option on page 622.

**pass-through** Copies files from one place on the system to another. Instead of constructing an archive file containing the files named on standard input, `cpio` copies them into the directory (the last argument given to `cpio`). The effect is the same as if you had created an archive with copy-out mode and then extracted the files with copy-in mode, but using pass-through mode avoids creating an archive. The following example copies the files in the working directory and all subdirectories into `/home/alex/code`:

```
$ find . -depth -print | cpio -pdm ~alex/code
```

**Other Options**

The remaining options alter the behavior of `cpio`. These options work with one or more of the preceding major options.

**resetaccesstime**

- `a` Resets the access times of source files after copying them so that they have the same access time after copying as they did before.
- `B (block)` Sets the block size to 5,120 bytes instead of the default 512 bytes.

**blocksize= n**

Sets the block size used for input and output to `n` 512-byte blocks.

- `c (compatible)` Writes header information in ASCII so that older (incompatible) `cpio` utilities on other systems can read the file. This option is rarely needed.

**makdirectories**

- `d` Creates directories as needed when copying files. For example, you need this option when you are extracting files from an archive with a file list generated by `find` with the `depth` option. This option can be used only with the `extract` and `passthrough` options.

**patternfile= filename**

- `E filename` Reads patterns from `filename`, one pattern per line. You can specify additional patterns on the command line.
- `n` (nonmatching) Reverses the sense of the test done on patterns when extracting files from an archive. Files are extracted from the archive only if they do not match any of the patterns.

**file= archive**

- `F archive` Uses `archive` as the name of the archive file. In extract mode, reads from `archive` instead of standard input. In create mode, writes to `archive` instead of standard output. You can use this option to access a device on another system on a network; see the `file` option to `tar` (page
Displays a list of options.

When possible, links files instead of copying them.

Copies the files that symbolic links point to, not the symbolic links themselves.

Preserves the modification times of files that are extracted from an archive. Without this option the files show the time they were extracted. With this option the created files show the time they had when they were copied into the archive.

In extract mode, creates all filenames relative to the working directory—even files that were archived with absolute pathnames.

Allows you to rename files as cpio copies them. When cpio prompts you with the name of a file, you respond with the new name. The file is then copied with the new name. If you press RETURN instead, cpio does not copy the file.

Displays a table of contents of the archive. This option works only with the extract option, although no files are actually extracted from the archive. With the verbose option, it displays a detailed table of contents in a format similar to that used by ls l.

Overwrites existing files regardless of their modification times. Without this option cpio will not overwrite a more recently modified file with an older one; it simply displays a warning message.

Lists files as they are processed. With the list option, it displays a detailed table of contents in a format similar to that used by ls l.

GNU cpio version 2.5 displays erroneous truncating inode number error messages; you can safely ignore these messages.

Without the unconditional option, cpio will not overwrite a more recently modified file with an older file.

You can use both ordinary and directory filenames as input when you create an archive. If the name of an ordinary file appears in the input list before the name of its parent directory, the ordinary file appears before its parent directory in the archive as well. This order can lead to an avoidable error: When you extract files from the archive, the child has nowhere to go in the file structure if its parent has not yet been extracted.

Making sure that files appear after their parent directories in the archive is not always a solution. One problem occurs if the preserve modification time option is used when extracting files. Because the modification time of a parent directory is updated whenever a file is created within it, the original modification time of the parent directory is lost when the first file is written to it.

The solution to this potential problem is to ensure that all files appear before their parent directories when creating an archive and to create directories as needed when extracting files from an archive. When you use this technique, directories are extracted only after all files have been written to them and their modification times are preserved.
With the \texttt{-depth} option, the \texttt{find} utility generates a list of files with all children appearing in the list before their parent directories. If you use this list to create an archive, the files are in the proper order. (Refer to the first example in the next section.) When extracting files from an archive, the \texttt{-makedirectories} option causes \texttt{cpio} to create parent directories as needed and the \texttt{-preserve-modification-time} option does just what its name says. Using this combination of utilities and options preserves directory modification times through a create/extract sequence.

This strategy also solves another potential problem. Sometimes a parent directory may not have permissions set so that you can extract files into it. When \texttt{cpio} automatically creates the directory with \texttt{-makedirectories}, you can be assured of write permission to the directory. When the directory is extracted from the archive (after all the files are written into the directory), it is extracted with its original permissions.

**Examples**

The first example creates an archive of the files in Jenny's home directory, writing the archive to a tape drive supported by the \texttt{ftape} driver:

\begin{verbatim}
$ find /home/jenny -depth -print | cpio -oB >/dev/ftape
\end{verbatim}

The \texttt{find} utility produces the filenames that \texttt{cpio} uses to build the archive. The \texttt{-depth} option causes all entries in a directory to be listed before listing the directory name itself, making it possible for \texttt{cpio} to preserve the original modification times of directories (see the preceding "Discussion."). Use the \texttt{-makedirectories} and the \texttt{-preserve-modification-time} when you extract files from this archive (see the following examples). The \texttt{-B} option blocks the tape at 5,120 bytes per block.

To check the contents of the archive file and display a detailed listing of the files it contains, use

\begin{verbatim}
$ cpio -itv < /dev/ftape
\end{verbatim}

The following command restores the files that formerly were in the \texttt{memo} subdirectory of Jenny's home directory:

\begin{verbatim}
$ cpio -idm /home/jenny/memo/* < /dev/ftape
\end{verbatim}

The \texttt{-d} (\texttt{-makedirectories}) option ensures that any subdirectories that were in the \texttt{memo} directory are re-created as needed. The \texttt{-m} (\texttt{-preserve-modification-time}) option preserves the modification times of files and directories. The asterisk in the regular expression is escaped to keep the shell from expanding it.

The next command is the same as the preceding command except that it uses the \texttt{-no-absolute-filenames} option to re-create the \texttt{memo} directory in the working directory, which is named \texttt{memocopy}. The pattern does not start with the slash that represents the root directory allowing \texttt{cpio} to create the files with relative pathnames.

\begin{verbatim}
$ pwd
/home/jenny/memocopy
$ cpio -idm -- no-absolute-filenames home/jenny/memo/* < /dev/ftape
\end{verbatim}

The final example uses the \texttt{-f} option to restore all the files in the archive except those that were formerly in the \texttt{memo} subdirectory:
$ cpio -ivmdf /home/jenny/memo/* < /dev/ftape

The `v` option lists the extracted files as `cpio` processes the archive, verifying that the expected files are extracted.

**crontab: Maintains crontab files**

`crontab [u user-name] filename`

`crontab [u user-name] option`

A crontab file associates periodic times (such as 14:00 on Wednesdays) with commands. The `cron` utility executes each command at the specified time. When you are working as yourself, the `crontab` utility installs, removes, lists, and edits your crontab file. Superuser can work with any user's crontab file.

**Arguments**

The first format copies the contents of `filename` (which contains crontab commands) into the crontab file of the user who runs the command. When the user does not have a crontab file, this process creates a new one; when the user has a crontab file, this process overwrites the file. When you replace `filename` with a hyphen (`-`), `crontab` reads commands from standard input.

The second format lists, removes, or edits the crontab file, depending on which option you specify.

**Options**

Choose only one of the `e`, `l`, or `r` options. Superuser can use `u` with one of these options.

- `e` *(edit)* Runs the text editor specified by the `VISUAL` or `EDITOR` shell variable on the crontab file, enabling you to add, change, or delete entries. Installs the modified crontab file when you exit from the editor.

- `l` *(list)* Displays the contents of the crontab file.

- `r` *(remove)* Deletes the crontab file.

- `u user-name` *(user)* Works on `user-name` 's crontab file. Only Superuser can use this option and Superuser should always use this option.

**Notes**

This section covers the versions of `cron`, `crond`, `crontab`, and crontab files that were written by Paul Vixie; hence the term Vixie cron. These versions differ from an earlier version of Vixie cron as well as from the classic SVR3 syntax. This version is POSIX compliant.

User crontab files are kept in the `/var/spool/cron` directory, each named with the username of the user that it belongs to, owned by `root`, and associated with the user's primary group.

The system utility named `cron` reads the crontab files and runs the commands. If a command line in a crontab file does not redirect its output, output sent to standard output and standard error are mailed to the user unless you set the `MAILTO` variable within the crontab file to a different username.
To make the system administrator's job easier, the directories named `/etc/cron.hourly`, `/etc/cron.daily`, `/etc/cron.weekly`, and `/etc/cron.monthly` hold crontab files that are run by `run-parts`, which in turn are run by the `/etc/crontab` file. Each of these directories contains files that execute system tasks at the interval named by the directory. Superuser can add files to these directories instead of adding lines to root's crontab file. A typical `/etc/crontab` file looks like this:

```bash
$ cat /etc/crontab

SHELL=/bin/bash
PATH=/sbin:/bin:/usr/sbin:/usr/bin
MAILTO=root
HOME=/

# run-parts
01 * * * * root run-parts /etc/cron.hourly
02 4 * * * root run-parts /etc/cron.daily
22 4 * * 0 root run-parts /etc/cron.weekly
42 4 1 * * root run-parts /etc/cron.monthly
```

Each entry in a crontab file begins with five fields that specify when the command is to run (minute, hour, day of the month, month, and day of the week). The `cron` utility interprets an asterisk appearing in place of a number as a wildcard representing all possible values. In the day-of-the-week field, you can use either 7 or 0 to represent Sunday.

It is a good practice to start `cron` jobs a variable number of minutes before or after the hour, half hour, or quarter hour. When you start them at these times, it becomes less likely that many processes will start at the same time, potentially overloading the system.

When `cron` starts (usually when the system is booted), it reads all of the crontab files into memory. The `cron` utility mostly sleeps but wakes up once a minute, reviews all crontab entries it has stored in memory, and runs whichever ones are due to be run at that time.

```
/etc/cron.allow /etc/cron.deny
```

Superuser determines which users can run `crontab` by creating, editing, and removing the `/etc/cron.allow` and `/etc/cron.deny` files. When you create a `cron.deny` file with no entries and no `cron.allow` file exists, everyone can use `crontab`. When the `cron.allow` file exists, only users listed in that file can use `crontab`, regardless of the presence and contents of `cron.deny`. Otherwise, you can list in the `cron.allow` file those users who should be able to use `crontab` and in `cron.deny` those who should not be able to use it. (Listing a user in `cron.deny` is not necessary because, if a `cron.allow` file exists and the user is not listed in it, the user will not be able to use `crontab` anyway.)
Examples

The following example uses `crontab -l` to list the contents of Jenny's crontab file (`/var/spool/cron/jenny`). All the scripts that Jenny runs are in her `~/bin` directory. The first line sets the `MAILTO` variable to `alex` so that Alex gets the output from commands run from Jenny's crontab file that is not redirected. The `sat.job` script runs every Saturday (day 6) at 2:05 AM, `twice.week` runs at 12:02 AM on Sunday and Thursday (days 0 and 4), and `twice.day` runs twice a day, every day, at 10 AM and 4 PM.

```
$ who am i
jenny

$ crontab -l
MAILTO=alex
05 02 * * 6        $HOME/bin/sat.job
00 02 * * 0,4      $HOME/bin/twice.week
05 10,16 * * *     $HOME/bin/twice.day
```

To add an entry to your crontab file, run the `crontab` utility with the `-e` (edit) option. Some Linux systems use a version of `crontab` that does not support the `-e` option. If the local system runs such a version, you need to make a copy of your existing `crontab` file, edit it, and then resubmit it, as in the example that follows. The `-l` (list) option displays a copy of your `crontab` file.

```
$ crontab -l > newcron
$ vim newcron
...
$ crontab newcron
```

**cut: Selects characters or fields from input lines**

```
cut [options] [file-list]
```

The `cut` utility selects characters or fields from lines of input and writes them to standard output. Character and field numbering start with 1.

**Arguments**

The `file-list` is a list of ordinary files. If you do not specify an argument or if you specify a hyphen (\(\)) in place of a filename, `cut` reads from standard input.
Options

Accepts the common options described on page 587.

characters=
c
clist

Selects the characters given by the column numbers in clist. The value of clist is one or more comma-separated column numbers or column ranges. A range is specified by two column numbers separated by a hyphen. A range of n means columns 1 through n; n means columns n through the end of the line.

delimiter=
d

Specifies dchar as the input field delimiter. Also specifies dchar as the output field delimiter unless you use the output-delimiter option. The default delimiter is a TAB character. Quote characters as necessary to protect them from shell expansion.

fields=
f
flist

Selects the fields specified in flist. The value of flist is one or more comma-separated field numbers or field ranges. A range is specified by two field numbers separated by a hyphen. A range of n means fields 1 through n; n means fields n through the last field. The field delimiter is a TAB character unless you use the delimiter option to change it.

output-delimiter=
o

Specifies ochar as the output field delimiter. The default delimiter is the TAB character. You can specify a different delimiter by using the delimiter option. Quote characters as necessary to protect them from shell expansion.

Notes

Although limited in functionality, cut is easy to learn and use and is a good choice when columns and fields can be selected without using pattern matching. Sometimes cut is used with paste (page 742).

Examples

For the next two examples, assume that an ls -l command produces the following output:

$ ls -l

total 2944
-rwxr-xr-x 1 zach pubs 259 Feb 1 00:12 countout
-rw-r--r-- 1 zach pubs 9453 Feb 4 23:17 headers
-rw-r--r-- 1 zach pubs 1474828 Jan 14 14:15 memo
-rw-r--r-- 1 zach pubs 1474828 Jan 14 14:33 memos_save
The following command outputs the permissions of the files in the working directory. The `cut` utility with the `-c` option selects characters 2 through 10 from each input line. The characters in this range are written to standard output.

```
$ ls -l | cut -c2-10
```

```
total 2944
-rwxr-xr-x
rw-rw-r--
-rw-rw-r--
-rw-rw-r--
-rw-rw-r--
-rw-rw-r--
-rw-rw-r--
-rw-rw-r--
```

The next command outputs the size and name of each file in the working directory. This time the `-f` option selects the fifth and ninth fields from the input lines. The `-d` option tells `cut` to use SPACES, not TABs, as delimiters. The `TR` utility (page 804) with the `-s` option changes sequences of more than one SPACE character into a single SPACE; otherwise, `cut` counts the extra SPACE characters as separate fields.

```
$ ls -l | tr -s ' ' ' ' | cut -f5,9 -d'
```

259 countout
9453 headers
1474828 memo
1474828 memos_save
7134 tmp1
4770 tmp2
13580 typescript
The last example displays a list of full names as stored in the fifth field of the `/etc/passwd` file. The `d` option specifies that the colon character be used as the field delimiter.

```
$ cat /etc/passwd
root:x:0:0:Root:/bin/sh
jenny:x:401:50:Jenny Chen:/home/jenny:/bin/zsh
alex:x:402:50:Alex Watson:/home/alex:/bin/bash
scott:x:504:500:Scott Adams:/home/scott:/bin/tcsh
hls:x:505:500:Helen Simpson:/home/hls:/bin/bash
```

```
$ cut -d: -f5 /etc/passwd
Root
Jenny Chen
Alex Watson
Scott Adams
Helen Simpson
```

**date: Displays or sets the system time and date**

```
date [options] [+format]
date [options] [newdate]
```

The `date` utility displays the time and date known to the system. Superuser can use `date` to change the system clock.

**Arguments**

The `+format` argument specifies the format for the output of `date`. The format string consisting of field descriptors and text follows a plus sign (+). The field descriptors are preceded by percent signs, and each one is replaced by its value in the output. Table V-10 lists some of the field descriptors.
<table>
<thead>
<tr>
<th>Descriptor</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Abbreviated weekday—Sun to Sat</td>
</tr>
<tr>
<td>%A</td>
<td>Unabbreviated weekday—Sunday to Saturday</td>
</tr>
<tr>
<td>%b</td>
<td>Abbreviated month—Jan to Dec</td>
</tr>
<tr>
<td>%B</td>
<td>Unabbreviated month—January to December</td>
</tr>
<tr>
<td>%c</td>
<td>Date and time in default format used by date</td>
</tr>
<tr>
<td>%d</td>
<td>Day of the month—01 to 31</td>
</tr>
<tr>
<td>%D</td>
<td>Date in mm/dd/yy format</td>
</tr>
<tr>
<td>%H</td>
<td>Hour—00 to 23</td>
</tr>
<tr>
<td>%I</td>
<td>Hour—00 to 12</td>
</tr>
<tr>
<td>%j</td>
<td>Julian date (day of the year—001 to 366)</td>
</tr>
<tr>
<td>%m</td>
<td>Month of the year—01 to 12</td>
</tr>
<tr>
<td>%M</td>
<td>Minutes—00 to 59</td>
</tr>
<tr>
<td>%n</td>
<td>NEWLINE character</td>
</tr>
<tr>
<td>%p</td>
<td>AM or PM</td>
</tr>
<tr>
<td>%r</td>
<td>Time in AM/PM notation</td>
</tr>
<tr>
<td>%s</td>
<td>Number of seconds since the beginning of January 1, 1970</td>
</tr>
<tr>
<td>%S</td>
<td>Seconds—00 to 60 (the 60 accommodates leap seconds)</td>
</tr>
<tr>
<td>%t</td>
<td>TAB character</td>
</tr>
<tr>
<td>%T</td>
<td>Time in HH:MM:SS format</td>
</tr>
<tr>
<td>%w</td>
<td>Day of the week—0 to 6 (0 = Sunday)</td>
</tr>
<tr>
<td>%y</td>
<td>Last two digits of the year—00 to 99</td>
</tr>
<tr>
<td>%Y</td>
<td>Year in four-digit format (for example, 2005)</td>
</tr>
<tr>
<td>%Z</td>
<td>Time zone (for example, PDT)</td>
</tr>
</tbody>
</table>

By default date zero fills numeric fields. Place an underscore (_) immediately following the percent sign (%) for a specific field to cause date to blank fill the field and with a hyphen (ı) to cause date not to fill the field—that is, to left justify the field.

The date utility assumes that, in a format string, any character that is not a percent sign, an underscore or a hyphen following the percent sign, or a field descriptor is ordinary text and copies it to standard output. You can use ordinary text to add punctuation to the date and to add labels (for example, you can put the word DATE: in front of the date). Surround the format argument with single quotation marks if it contains SPACE s or other characters that have a special meaning to the shell.

Setting the date

When Superuser specifies newdate, the system changes the system clock to reflect the new date. The newdate argument has the format

```
nnddhhmm[[cc]yy][.ss]
```

where nn is the number of the month (01–12), dd is the day of the month (01–31), hh is the hour based on a 24-hour clock (00–23), and mm is the minutes (00–59). When you change the date, you must specify at least these fields.

The optional cc specifies the first two digits of the year (the value of the century minus 1), and yy specifies the last two digits of the year. You can specify yy or ccyy following mm. When you do not specify a year, date assumes
that the year has not changed.

You can specify the number of seconds past the start of the minute with .ss.

Options

Accepts the common options described on page 587.

```
reference= file     Displays the modification date and time of file in place of the current date and time.
utc or universal    Displays or sets the time and date using Universal Coordinated Time (UTC, page 908; also called Greenwich Mean Time [GMT]).
```

Notes

If you set up a locale database, date uses that database to substitute terms appropriate to your locale (page 885).

Examples

The first example shows how to set the date for 2:07:30 PM on August 19 without changing the year:

```
# date 08191407.30
Sat Aug 19 14:07:30 PDT 2005
```

The next example shows the format argument, which causes date to display the date in a commonly used format:

```
$ date '+Today is %h %d, %Y'
Today is Aug 19, 2005
```

dd: Converts and copies a file

dd [arguments]

The dd (device-to-device copy) utility converts and copies a file. The primary use of dd is to copy files to and from such devices as tape and floppy drives. Often dd can handle the transfer of information to and from other operating systems when other methods fail. A rich set of arguments gives you precise control over the characteristics of the transfer.

Arguments

Accepts the common options described on page 587.
By default `dd` copies standard input to standard output.

- **bs= n**  
  *(block size)* Reads and writes `n` bytes at a time. This argument overrides the `ibs` and `obs` arguments.

- **cbs= n**  
  *(conversion block size)* When performing data conversion during the copy, converts `n` bytes at a time.

- **Conv= type [, type…]**  
  By applying conversion `type` s in the order given on the command line, converts the data that is being copied. The `type` s must be separated by commas with no SPACEs. The types of conversions are shown in Table V-11.

- **count= numblocks**  
  Restricts to `numblocks` the number of blocks of input that `dd` copies. The size of each block is the number of bytes specified by the `ibs` argument.

- **ibs= n**  
  *(input block size)* Reads `n` bytes at a time.

- **if= filename**  
  *(input file)* Reads from `filename` instead of from standard input. You can use a device name for `filename` to read from that device.

- **obs= n**  
  *(output block size)* Writes `n` bytes at a time.

- **of= filename**  
  *(output file)* Writes to `filename` instead of to standard output. You can use a device name for `filename` to write to that device.

- **seek= numblocks**  
  Skips `numblocks` blocks of output before writing any output. The size of each block is the number of bytes specified by the `obs` argument.

- **skip= numblocks**  
  Skips `numblocks` blocks of input before starting to copy. The size of each block is the number of bytes specified by the `ibs` argument.

| Table V-11. Conversion types |
|-----------------------------|----------------|
| **type**                    | **Meaning**                                           |
| ascii                       | Converts EBCDIC-encoded characters to ASCII, allowing you to read tapes written on IBM mainframe and similar computers. |
| block                      | Each time a line of input is read (that is, a sequence of characters terminated with a NEWLINE character), outputs a block of text without the NEWLINE. Each output block has the size given by the `obs` or `bs` argument and is created by adding trailing SPACE characters to the text until it is the proper size. |
| ebc dic                    | Converts ASCII-encoded characters to EBCDIC, allowing you to write tapes for use on IBM mainframe and similar computers. |
| unblock                    | Performs the opposite of the block conversion. |
| lcase                      | Converts uppercase letters to lowercase while copying data. |
| noerror                    | If a read error occurs, `dd` normally terminates. This conversion allows `dd` to continue processing data. This conversion is useful when you are trying to recover data from bad media. |
| notrunc                    | Does not truncate the output file before writing to it. |
| ucase                      | Converts lowercase letters to uppercase while copying data. |

**Notes**

You can use the standard multiplicative suffixes to make it easier to specify large block sizes. See Table V-1 on page 586.

**Examples**
You can use `dd` to create a file filled with pseudo-random bytes.

```bash
$ dd if=/dev/urandom of=randfile2 bs=1 count=100
```

The preceding command reads from the `/dev/urandom` file (an interface to the kernel's random number generator) and writes to the file named `randfile`. The block size is 1 and the count is 100 so `randfile` is 100 bytes long. For bytes that are more random, you can read from `/dev/random`. See the `urandom` and `random` man pages for more information.

**Wiping a file**

You can use a similar technique to wipe data from a file before deleting it, making it almost impossible to recover data from a deleted file. You might want to wipe a file for security reasons. Wipe a file several times for added security.

In the following example, `ls` shows the size of the file named `secret`; `dd`, with a block size of 1 and a count corresponding to the number of bytes in `secret`, then wipes the file. The `conv=notrunc` argument ensures that `dd` writes over the data in the file and not another place on the disk.

```bash
$ ls -l secret
-rw-rw-r--  1 max max 2494 Feb  6 00:56 secret
$ dd if=/dev/urandom of=secret bs=1 count=2494 conv=notrunc
2494+0 records in
2494+0 records out
$ rm secret
```

**Copying a diskette**

You can use `dd` to make an exact copy of a floppy diskette. First copy the contents of the diskette to a file on the hard drive and then copy the file from the hard disk to a formatted diskette. This technique works regardless of what is on the floppy diskette. The next example copies a DOS-formatted diskette. The `mount, ls, umount` sequences at the beginning and end of the example verify that the original diskette and the copy hold the same files. You can use the `floppy.copy` file to make multiple copies of the diskette.

```bash
# mount -t msdos /dev/fd0H1440 /mnt
# ls /mnt
abprint.dat bti.ini setup.ins supfiles.z wbt.z
adbook.z setup.exe setup.pkg telephon.z
# umount /mnt
```
# dd if=/dev/fd0 ibs=512 > floppy.copy

2880+0 records in
2880+0 records out

# ls -l floppy.copy
-rw-rw-r--   1 alex speedy 1474560 Oct 11 05:43 floppy.copy

# dd if=floppy.copy bs=512 of=/dev/fd0

2880+0 records in
2880+0 records out

# mount -t msdos /dev/fd0H1440 /mnt

# ls /mnt
abprint.dat  bti.ini      setup.ins    supfiles.z   wbt.z
adbook.z     setup.exe    setup.pkg    telephon.z

# umount /mnt

df: Displays disk space usage

df [options] [filesystem-list]

The df (disk free) utility reports on the total space and the free space on each mounted device.

Arguments

When you call df without an argument, it reports on the free space on each of the currently mounted devices.

The **filesystem-list** is an optional list of one or more pathnames that specify the filesystems you want the report to cover. You can refer to a mounted filesystem by its device pathname or by the pathname of the directory it is mounted on.
Options

- **all**
  - Reports on filesystems with a size of 0 blocks, such as /dev/proc. Normally `df` does not report on these filesystems.

- **block-size= sz**
  - The `sz` specifies the units that the report uses (the default is 1-kilobyte blocks). For example, `block-size=M` displays sizes in 1,048,576-byte units while `block-size=MB` displays sizes in 1,000,000-byte units. See Table V-1 on page 586 for a complete list of multiplicative suffixes. See also the `human-readable` option.

- **human-readable**
  - `h` Displays sizes in K (kilobyte), M (megabyte), and G (gigabyte) blocks, as is appropriate. Uses powers of 1,024; use `si` for powers of 1,000.

- **inodes**
  - `i` Reports the number of inodes (page 880) that are used and free instead of reporting on blocks.

- **local**
  - `l` Displays local filesystems only.

- **type= fstype**
  - `t` Reports information only about the filesystems of type `fstype`, such as DOS or NFS. Repeat this option to report on several types of filesystems.

- **exclude-type= fstype**
  - `x` Reports information only about the filesystems not of type `fstype`.

Examples

In the following example, `df` displays information about all mounted filesystems on the local system:

```
$ df

Filesystem    1k-blocks  Used  Available  Use%  Mounted on
/dev/hda12    1517920   53264   1387548   4%   /
/dev/hda1      15522    4846    9875   33%  /boot
/dev/hda8     1011928  110268   850256   11%  /free1
/dev/hda9     1011928   30624   929900    3%  /free2
/dev/hda10    1130540   78992   994120    7%  /free3
/dev/hda5     4032092  1988080  1839188   52%  /home
/dev/hda7     1011928     60   960464    0%   /tmp
/dev/hda6     2522048  824084  1569848   34%  /usr
zach:/c       2096160  1811392   284768   86%  /zach_c
zach:/d       2096450  1935097  161353   92%  /zach_d
```
Next `df` is called with the `-l` and `-h` options, generating a human-readable list of local filesystems. The sizes in this listing are given in terms of megabytes and gigabytes. The NFS mounted filesystems (from `zach`) are not visible.

```
$ df -lh

Filesystem     Size  Used  Avail  Use%  Mounted on
/dev/hda12    1.4G   52M  1.3G    4%  /
/dev/hda1      15M   4.7M  9.6M   33%  /boot
/dev/hda8      988M  108M  830M   11%  /free1
/dev/hda9      988M  30M   908M    3%  /free2
/dev/hda10     1.1G   77M  971M    7%  /free3
/dev/hda5      3.8G   1.9G  1.8G   52%  /home
/dev/hda7      988M   60k  938M    0%  /tmp
/dev/hda6      2.4G  805M  1.5G   34%  /usr
```

The next example displays information about the `/free2` partition in megabyte units:

```
$ df -BM /free2

Filesystem     1M-blocks       Used     Available  Use%  Mounted on
/dev/hda9        988         30       908     3%  /free2
```

The final example displays information about NFS filesystems in human-readable terms:

```
$ df -ht nfs

Filesystem     Size  Used  Avail  Use%  Mounted on
zach:/c        2.0G   1.7G  278M   86%  /zach_c
zach:/d        2.0G   1.8G  157M   92%  /zach_d
```

diff: Displays the differences between two files

```
diff [options] file1 file2
diff [options] file1 directory
```
diff [options] directory file2
diff [options] directory1 directory2

The **diff** utility displays line-by-line differences between two files. By default **diff** displays the differences as instructions you can use to edit one of the files to make it the same as the other.

### Arguments

The **file1** and **file2** are pathnames of ordinary files that **diff** works on. When the **directory** argument is used in place of **file2**, **diff** looks for a file in **directory** with the same name as **file1**. It works similarly when **directory** replaces **file1**. When you specify two directory arguments, **diff** compares the files in **directory1** with the files that have the same simple filenames in **directory2**.

### Options

Accepts the [common options](man587) described on page 587, with one exception: When one of the arguments is a directory and the other is an ordinary file, you cannot compare to standard input.

- **ignore-space-change**
  - `-b` Ignores whitespace (SPACE s and TAB s) at the ends of lines and considers other strings of whitespace to be equal.

- **ignore-blank-lines**
  - `-B` Ignores differences that involve only blank lines.

- **context [= lines]**
  - `-C` Displays the sections of the two files that differ, including *lines* lines (the default is 3) around each line that differs to show the context. Each line in **file1** that is missing from **file2** is preceded by `-`; each extra line in **file2** is preceded by `+`; and lines that have different versions in the two files are marked with `!`. When lines that differ are within *lines* lines of each other, they are grouped together in the output.

- **ed**
  - `-e` Creates and sends to standard output a script for the **ed** editor, which will edit **file1** to make it the same as **file2**. You must add `w` (write) and `q` (quit) instructions to the end of the script if you plan to redirect input to **ed** from the script. When you use `-ed`, **diff** displays the changes in reverse order: Changes to the end of the file are listed before changes to the top, preventing early changes from affecting later changes when the script is used as input to **ed**. For example, if a line near the top were deleted, subsequent line numbers in the script would be wrong.

- **ignore-case**
  - `-i` Ignores differences in case when comparing files.

- **new-file**
  - `-N` When comparing directories, when a file is present in one of the directories only, considers it to be present and empty in the other directory.

- **show-c-function**
  - `-p` Shows which C function each change affects.

- **brief**
  - `-q` Does not display the differences between lines in the files. Instead, **diff** reports only that the files differ.

- **recursive**
  - `-r` When using **diff** to compare the files in two directories, causes the comparisons to extend through subdirectories as well.

- **unified[= lines]**
  - `-U` **Lines**
    Uses the easier-to-read unified output format. See the discussion of **diff** on page 51 for more detail and an example. The *lines* is the number of lines of context; the default
is three.

**ignore-all-space**

- **w** (whitespace) Ignores whitespace when comparing lines.

**width= columns**

- **W** _columns_

  Sets the width of the columns that **diff** uses to display the output to **columns**. This option is useful with the **side-by-side** option. The **sdiff** utility uses a lowercase **w** to perform the same function: **w columns**.

**side-by-side**

- **y**

  Displays output in a side-by-side format. This option generates the same output as **sdiff**. Use the **width= columns** option with this option.

**Notes**

The **sdiff** utility is similar to **diff** but its output may be easier to read. The **diff** **side-by-side** option produces the same output as **sdiff**. See the "Examples" section and refer to the **diff** and **sdiff man** and info pages for more information.

You can use the **diff3** utility to compare three files.

**Discussion**

When you use **diff** without any options, it produces a series of lines containing Add (a), Delete (d), and Change (c) instructions. Each of these lines is followed by the lines from the file that you need to add, delete, or change to make the files the same. A less than symbol (<) precedes lines from **file1**. A greater than symbol (>) precedes lines from **file2**. The **diff** output appears in the format shown in Table V-12. A pair of line numbers separated by a comma represents a range of lines; a single line number represents a single line.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Meaning (to change file1 to file2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>line1 a line2, line3</td>
<td>Append lines line2 through line3 from <strong>file2</strong> after line1 in <strong>file1</strong>.</td>
</tr>
<tr>
<td>&gt; lines from file2</td>
<td></td>
</tr>
<tr>
<td>line1,line2 d line3</td>
<td>Delete line1 through line2 from <strong>file1</strong>.</td>
</tr>
<tr>
<td>&lt; lines from file1</td>
<td></td>
</tr>
<tr>
<td>line1,line2 c line3,line4</td>
<td>Change line1 through line2 in <strong>file1</strong> to line3 through line 4 from <strong>file2</strong>.</td>
</tr>
<tr>
<td>&lt; lines from file1</td>
<td></td>
</tr>
<tr>
<td>Instruction</td>
<td>Meaning (to change file1 to file2)</td>
</tr>
<tr>
<td>-------------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td>&gt; lines from file 2</td>
<td></td>
</tr>
</tbody>
</table>

The `diff` utility assumes that you will convert `file1` to `file2`. The line numbers to the left of each of the `a`, `c`, or `d` instructions always pertain to `file1`; the line numbers to the right of the instructions apply to `file2`. To convert `file2` to `file1`, run `diff` again, reversing the order of the arguments.

**Examples**

The first example shows how `diff` displays the differences between two short, similar files:

```
$ cat m
aaaaa
bbbbb
cccccc

$ cat n
aaaaa
cccccc

$ diff m n
2d1
< bbbbbb
```

The difference between files `m` and `n` is that the second line of file `m` (`bbbbb`) is missing from file `n`. The first line that `diff` displays (`2d1`) indicates that you need to delete the second line from `file1` (m) to make it the same as `file2` (n). The next line `diff` displays starts with a less than symbol (`<`), indicating that this line of text is from `file1`. In this example, you do not need this information—all you need to know is the line number so that you can delete the line.

The `side-by-side` option and the `sdiff` utility, both with the output width set to 30 columns (characters), display the same output. In the output a less than symbol points to the extra line in file `m`, whereas `diff/sdiff` leaves a blank line in file `n` where the extra line would go to make the files the same.
$ diff --side-by-side --width=30 m n

```
  aaaaa     aaaaa
 bbbbbb     <
 cccccc     cccccc
```

$ sdiff -w 30 m n

```
  aaaaa     aaaaa
 bbbbbb     <
 cccccc     cccccc
```

The next example uses the same m file and a new file, p, to show diff issuing an a (append) instruction:

```
$ cat p
aaaaa
 bbbbbb
  rrrrr
 cccccc
```

$ diff m p

```
2a3
  > rrrrr
```

In the preceding example, diff issues the instruction 2a3 to indicate that you must append a line to file m, after line 2, to make it the same as file p. The second line that diff displays indicates that the line is from file p (the line begins with >, indicating file2). In this example, you need the information on this line; the appended line must contain the text rrrrr.

The next example uses file m again, this time with file r, to show how diff indicates a line that needs to be changed:

```
$ cat r
aaaaa
    -q
```
$ diff m r
2c2
< bbbbbb
---
> -q

The difference between the two files is in line 2: File \texttt{m} contains \texttt{bbbbb}, and file \texttt{r} contains \texttt{q}. The \texttt{diff} utility displays \texttt{2c2} to indicate that you need to change line 2. After indicating that a change is needed, \texttt{diff} shows that you must change line 2 in file \texttt{m (bbbbb)} to line 2 in file \texttt{r (q)} to make the files the same. The three hyphens indicate the end of the text in file \texttt{m} that needs to be changed and the start of the text in file \texttt{r} that is to replace it.

Comparing the same files using the side-by-side and width options (\texttt{-y} and \texttt{-W}) yields an easier-to-read result. The pipe symbol (\texttt{|}) indicates that the line on one side must replace the line on the other side to make the files the same:

$ diff -y -W 30 m r
aaaaa           aaaaa
bbbbb         | -q
cccccc           cccccc

The next examples compare the two files \texttt{q} and \texttt{v}:

$ cat q $ cat v
Monday          Monday
Tuesday         Wednesday
Wednesday       Thursday
Thursday        Thursday
Saturday        Friday
Sunday          Saturday
Sundae

Running in side-by-side mode \texttt{diff} shows that \texttt{Tuesday} is missing from file \texttt{v}, there is only one \texttt{Thursday} in file
Running in side-by-side mode
diff shows that Tuesday is missing from file q, there is only one Thursday in file q (there are two in file v), and Friday is missing from file q. The last line is Sunday in file q and Sundae in file v: diff indicates that these lines are different. You can change file q to be the same as file v by removing Tuesday, adding one Thursday and Friday, and substituting Sundae from file v for Sunday from file q. Alternatively, you can change file v to be the same as file q by adding Tuesday, removing one Thursday and Friday, and substituting Sunday from file q for Sundae from file v.

```
$ diff -y -W 30 q v
Monday Monday
Tuesday <
Wednesday Wednesday
Thursday Thursday
  > Thursday
  > Friday
Saturday Saturday
Sunday | Sundae
```

**Context diff**

With the `--context` option (called a context diff), diff displays output that tells you how to turn the first file into the second. The top two lines identify the files and show that q is represented by asterisks, whereas v is represented by hyphens. Following a row of asterisks that indicates the start of a hunk of text is a row of asterisks with the numbers 1,6 in the middle. This line indicates that the instructions in the first section tell you what to remove from or change in file q (namely, lines 1 through 6 (that is, all the lines of file q; in a longer file it would mark the first hunk). The hyphen on the next line means that you need to remove the line with Tuesday. The line with an exclamation point indicates that you need to replace the line with Sunday with the corresponding line from file v. The row of hyphens with the numbers 1,7 in the middle indicates that the next section tells you which lines from file v (lines 1 through 7) you need to add or change in file q. You need to add a second line with Thursday and a line with Friday, and you need to change Sunday in file q to Sundae (from file v).

```
$ diff --context q v
*** q  Mon Aug 22 18:26:45 2005
--- v  Mon Aug 22 18:27:55 2005
***************
*** 1,6 ****
Monday
```
du: Displays information on disk usage by file

du [options] [path-list]

The du (disk usage) utility reports how much disk space is occupied by a directory (along with all its subdirectories and files) or a file. By default du displays the number of 1,024-byte blocks that are occupied by the directory or file.

Arguments

Without any arguments, du displays information about the working directory and its subdirectories. The path-list specifies the directories and files you want information on.

Options

Without any options, du displays the total storage used for each argument in path-list. For directories du displays this total after recursively listing the totals for each subdirectory.

- **all**
- **a** Displays the space used by all ordinary files along with the total for each directory.
- **block-size= sz**
- **B sz**

The sz specifies the units the report uses. For example, **block-size=M** displays sizes in 1,048,576-byte units while **block-size=MB** displays sizes in 1,000,000-byte units. See Table V-1 on page 586 for a complete list of multiplicative suffixes. See also the **human-readable** option.
**Total**

Displays a grand total at the end of the output.

**Human-readable**

Displays sizes in K (kilobyte), M (megabyte), and G (gigabyte) blocks, as appropriate. Uses powers of 1,024; use `si` for powers of 1,000.

**Kilobytes**

Displays sizes in 1-kilobyte blocks.

**Dereference**

Includes the sizes of the files symbolic links point to, not the symbolic links themselves. The default is `no-dereference`.

**Megabytes**

Displays sizes in 1-megabyte blocks.

**No-dereference**

Includes the sizes of symbolic links, not the files that the links point to (default).

**Summarize**

Displays only the total size for each directory or file you specify on the command line; subdirectory totals are not displayed.

**One-file-system**

Reports only on files and directories on the same filesystem as that of the argument being processed.

**Examples**

In the first example, `du` displays size information about subdirectories in the working directory. The last line contains the grand total for the working directory and its subdirectories.

```
$ du
26 ./Postscript
  4 ./RCS
 47 ./XIcon
  4 ./Printer/RCS
 12 ./Printer
 105 .
```

The total (105) is the number of blocks occupied by all plain files and directories under the working directory. All files are counted, even though `du` displays only the sizes of directories.

Next using the `summarize` option, `du` displays the total for each of the directories in `/home` but not for any subdirectories:

```
# du --summarize /home/*
68 /home/Desktop
1188 /home/doug
100108 /home/dump
62160 /home/ftp
```
Add to the previous example the `--total` option and you get the same listing with a grand total at the end:

```
# du --summarize --total /home/*
```

```
68     /home/Desktop
...
4     /home/tom
2032456 total
```

If you do not have read permission for a file or directory that `du` encounters, `du` sends a warning to standard error and skips that file or directory. The following example uses the `s` (summarize), `h` (human-readable), and `c` (total) options:

```
$ du -shc /usr/*
```

```
112M   /usr/X11R6
161M   /usr/bin
4.0K   /usr/dict
4.0K   /usr/doc
4.0K   /usr/etc
3.9M   /usr/games
...
```

`du: cannot change to directory '/usr/lost+found': Permission denied`
30M /usr/sbin

du: cannot change to directory '/usr/share/ssl/CA': Permission denied

797M /usr/share

188M /usr/src

2.2G total

The final example displays, in human-readable format, the total size of all the files the user can read in the /usr filesystem. Redirecting standard error to /dev/null discards all warnings about files and directories that are unreadable.

$ du --human-readable --summarize /usr 2>/dev/null

2.2G /usr

echo: Displays a message

echo [options] message

The echo utility copies its arguments, followed by a NEWLINE, to standard output. The Bourne Again and TC Shells each has an echo builtin that works similarly to the echo utility.

Arguments

The message consists of one or more arguments, which can include quoted strings, ambiguous file references, and shell variables. A SPACE separates each argument from the next. The shell recognizes unquoted special characters in the arguments. For example, the shell expands an asterisk into a list of filenames in the working directory.

Options

You can configure the tcsh echo builtin to treat backslash escape sequences and the \n option in different ways. Refer to echo_style in the tcsh man page. The typical tcsh configuration recognizes the \n option, enables backslash escape sequences, and ignores the \e and \E options.

\e Enables the interpretation of backslash escape sequences such as \n.
\E Suppresses the interpretation of backslash escape sequences such as \n (bash and utility default).
\help Gives a short summary of how to use echo. The summary includes a list of the backslash escape sequences interpreted by echo. This option works only with the echo utility (/bin/echo) and not with the echo builtins.
\n Suppresses the NEWLINE terminating the message.

Notes
You can use `echo` to send messages to the screen from a shell script. See page 129 for a discussion of how to use `echo` to display filenames using wildcard characters.

The `echo` utility and builtins provide an escape notation to represent certain nonprinting characters in *message* (Table V-13). You must use the `e` option in order for these backslash escape sequences to work with the `echo` utility and the `bash echo` builtin. Typically you do not need the `e` option with the `tcsh echo` builtin.

### Table V-13. Backslash escape sequences

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\a</code></td>
<td>Bell</td>
</tr>
<tr>
<td><code>\c</code></td>
<td>Suppress trailing NEWLINE</td>
</tr>
<tr>
<td><code>\n</code></td>
<td>NEWLINE</td>
</tr>
<tr>
<td><code>\t</code></td>
<td>HORIZONTAL TAB</td>
</tr>
<tr>
<td><code>\v</code></td>
<td>VERTICAL TAB</td>
</tr>
<tr>
<td><code>\</code></td>
<td>BACKSLASH</td>
</tr>
</tbody>
</table>

#### Examples

Following are some `echo` commands. These commands will work with the `echo` utility (`/bin/echo`) and the `bash` and `tcsh echo` builtins, except for the last, which may not need the `e` option under `tcsh`.

```bash
$ echo "This command displays a string."
This command displays a string.

$ echo -n "This displayed string is not followed by a NEWLINE."
This displayed string is not followed by a NEWLINE.$ echo hi
hi

$ echo -e "This message contains\v a vertical tab."
This message contains

        a vertical tab.

$
```

The following examples contain messages with the backslash escape sequence `\c`. In the first example, the shell processes the arguments before calling `echo`. When the shell sees the `\c`, it replaces the `\c` with the character `c`. The next three examples show how to quote the `\c` so that the shell passes it to `echo`, which then does not append a NEWLINE to the end of the message. The first four examples are run under `bash` and require the `e` option. The final example runs under `tcsh`, which typically does not use this option.
You can use the `n` option in place of `e` and `c`.

**expr: Evaluates an expression**

```
expr expression
```

The `expr` utility evaluates an expression and sends the result to standard output. It evaluates character strings that represent either numeric or nonnumeric values. Operators are used with the strings to form expressions.

**Arguments**

The **expression** is composed of strings interspersed with operators. Each string and operator constitute a distinct argument that you must separate from other arguments with a SPACE. You must quote operators that have special meanings to the shell (for example, the multiplication operator, `*`).

The following list of `expr` operators is given in order of decreasing precedence. Each operator within a group of operators has the same precedence. You can change the order of evaluation by using parentheses.

1. **(comparison)** Compares two strings, starting with the first character in each string and ending with the last character in the second string. The second string is a regular expression with an implied caret (`^`) as its first
character. If there is a match, `expr` displays the number of characters in the second string. If there is no match, `expr` displays a zero.

* (multiplication)
/ (division)
% (remainder)

Work only on strings that contain the numerals 0 through 9 and optionally a leading minus sign. Convert strings to integer numbers, perform the specified arithmetic operation on numbers, and convert the result back to a string before sending it to standard output.

+ (addition)
- (subtraction)

Function in the same manner as the preceding group of operators.

< (less than)
<= (less than or equal to)
= or == (equal to)
!= (not equal to)
>= (greater than or equal to)
> (greater than)

Relational operators work on both numeric and nonnumeric arguments. If one or both of the arguments are nonnumeric, the comparison is nonnumeric, using the machine collating sequence (typically ASCII). If both arguments are numeric, the comparison is numeric. The `expr` utility displays a 1 (one) if the comparison is true and a 0 (zero) if it is false.

& (AND) Evaluates both of its arguments. If neither is 0 or a null string, `expr` displays the value of the first argument. Otherwise, it displays a 0. You must quote this operator.

| (OR) Evaluates the first argument. If it is neither 0 nor a null string, `expr` displays the value of the first argument. Otherwise, it displays the value of the second argument. You must quote this operator.

Notes

The `expr` utility returns an exit status of 0 (zero) if the expression evaluates to other than a null string or the number 0, a status of 1 if the expression is null or 0, and a status of 2 if the expression is invalid.

Although `expr` and this discussion distinguish between numeric and nonnumeric arguments, all arguments to `expr` are nonnumeric (character strings). When applicable, `expr` attempts to convert an argument to a number (for example, when using the + operator). If a string contains characters other than 0 through 9 with an optional leading minus sign, `expr` cannot convert it. Specifically, if a string contains a plus sign or a decimal point, `expr` considers it to be nonnumeric. If both arguments are numeric, the comparison is numeric. If one is nonnumeric, the comparison is lexicographic.

Examples

The following examples show command lines that call `expr` to evaluate constants. You can also use `expr` to evaluate variables in a shell script. The fourth command displays an error message because of the illegal decimal point in 5.3:

```
$ expr 17 + 40
57
```
$ expr 10 - 24
-14

$ expr -17 + 20
3

$ expr 5.3 + 4
expr: non-numeric argument

The multiplication (*), division (/), and remainder (%) operators provide additional arithmetic power. You must quote the multiplication operator (precede it with a backslash) so that the shell will not treat it as a special character (an ambiguous file reference). You cannot put quotation marks around the entire expression because each string and operator must be a separate argument.

$ expr 5 \* 4
20

$ expr 21 / 7
3

$ expr 23 % 7
2

The next two examples show how parentheses change the order of evaluation. You must quote each parenthesis and surround the backslash/parenthesis combination with SPACES:

$ expr 2 \* 3 + 4
10

$ expr 2 \* ( 3 + 4 )
14

You can use relational operators to determine the relationship between numeric or nonnumeric arguments. The following commands compare two strings to see if they are equal; expr displays a 0 when the relationship is false and a 1 when it is true.

$ expr fred == sam
0
$ expr sam == sam
1

In the following examples, the relational operators, which must be quoted, establish order between numeric or nonnumeric arguments. Again, if a relationship is true, `expr` displays a 1.

$ expr fred \> sam
0

$ expr fred \< sam
1

$ expr 5 \< 7
1

The next command compares 5 with m. When one of the arguments that `expr` is comparing with a relational operator is nonnumeric, `expr` considers the other to be nonnumeric. In this case because m is nonnumeric, `expr` treats 5 as a nonnumeric argument. The comparison is between the ASCII (on many systems) values of m and 5. The ASCII value of m is 109 and that of 5 is 53, so `expr` evaluates the relationship as true.

$ expr 5 \< m
1

The next example shows the matching operator determining that the four characters in the second string match the first four characters in the first string. The `expr` utility displays the number of matching characters (4).

$ expr abcdefghijkl : abcd
4

The & operator displays a 0 if one or both of its arguments are 0 or a null string; otherwise, it displays the first argument:

$ expr '' \& book
0
$ expr magazine \& book
magazine

$ expr 5 \& 0
0

$ expr 5 \& 6
5

The | operator displays the first argument if it is not 0 or a null string; otherwise, it displays the second argument:

$ expr '' | book
book

$ expr magazine | book
magazine

$ expr 5 | 0
5

$ expr 0 | 5
5

$ expr 5 | 6
5

file: Displays the classification of a file

file [option] file-list
The **file** utility classifies files according to their contents.

**Arguments**

The **file-list** is a list of the pathnames of one or more files that **file** classifies. You can specify any kind of file, including ordinary, directory, and special files, in the **file-list**.

**Options**

- **files-from= file**
  - Takes the names of files to be examined from **file** rather than from **file-list** on the command line. The names of the files must be listed one per line in **file**.

- **mime**
  - Displays **MIME** (page 887) type strings.

- **help**
  - Displays a help message.

- **dereference**
  - Reports on the files that symbolic links point to, not on the symbolic links themselves. The default is **no-dereference**.

- **uncompress**
  - Attempts to classify files within a compressed file.

**Notes**

The **file** utility can classify more than 5,000 file types. Some of the more common file types found on Linux systems, as displayed by **file**, are

- **archive**
- **ascii text**
- **c program text**
- **commands text**
- **core file**
- **cpio archive**
- **data**
- **directory**
- **ELF 32-bit LSB executable**
- **empty**
- **English text**
- **executable**
The `file` utility uses a maximum of three tests in its attempt to classify a file: filesystem, magic number, and language tests. When `file` identifies the type of a file, it ceases testing. The filesystem test examines the return from a `stat` system call to see whether the file is empty or a special file. The `magic number` (page 886) test looks for data in particular fixed formats near the beginning of the file. The language test, if needed, determines whether the file is a text file, what encoding it uses, and what language it is written in. Refer to the `file` man page for a more detailed description of how `file` works. The results of `file` are not always correct.

Examples

Some examples of file identification follow:

```
/etc/DIR_COLORS:    ASCII English text
/etc/X11:           directory
/etc/aliases.db:    regular file, no read permission
/etc/anacrontab:    ASCII text
/etc/asound.state:  ASCII text, with very long lines
/etc/at.deny:       empty
/etc/auto.net:      Bourne shell script text executable
/etc/grub.conf:     symbolic link to '../boot/grub/grub.conf'
/etc/localtime:     timezone data
/etc/named.conf:    C++ program text
/etc/rpc:           ASCII C program text
/etc/vimrc:         Composer 669 Module sound data
/usr/bin/GET:       perl script text executable
/usr/bin/HtFileType: Bourne shell script text executable
/usr/bin/Maelstrom: ELF 32-bit LSB executable, Intel 80386, version 1 (SYSV), for GNU/Linux 2.2.5, dynamically linked (uses shared libs), stripped
/usr/bin/X11:       symbolic link to '../X11R6/bin'
/usr/bin/[:         ELF 32-bit LSB executable, Intel 80386, version 1 (SYSV), for GNU/Linux 2.2 .5, dynamically linked (uses shared libs), stripped
```
find: Finds files based on criteria

find [directory-list] [expression]

The find utility selects files that are located in specified directory hierarchies and that meet specified criteria.

Arguments

The directory-list specifies the directories that find is to search. When find searches a directory, it searches all subdirectories to all levels. When you do not specify a directory-list, find searches the working directory.

The expression contains criteria, as described in the "Criteria" section. The find utility tests each of the files in each of the directories in the directory-list to see whether it meets the criteria described by the expression. When you do not specify an expression, the expression defaults to print.

A SPACE separating two criteria is a Boolean AND operator: The file must meet both criteria to be selected. An or or or separating the criteria is a Boolean OR operator: The file must meet one or the other (or both) of the criteria to be selected.

You can negate any criterion by preceding it with an exclamation point. The find utility evaluates criteria from left to right unless you group them using parentheses.
Within the expression you must quote special characters so that the shell will not interpret them but rather passes them to find. Special characters that you may frequently use with find are parentheses, brackets, question marks, and asterisks.

Each element within the expression is a separate argument. You must separate arguments from each other with SPACEs. There must be a SPACE on both sides of each parenthesis, exclamation point, criterion, or other element.

Criteria

You can use the following criteria within the expression. As used in this list, \( \pm n \) is a decimal integer that can be expressed as \( + n \) (more than \( n \)), \( - n \) (fewer than \( n \)), or \( n \) (exactly \( n \)).

\( \text{anewer filename} \)
(\text{accessed newer}) The file being evaluated meets this criterion if it was accessed more recently than filename.

\( \text{a time } \pm n \)
(\text{access time}) The file being evaluated meets this criterion if it was last accessed \( \pm n \) days ago. When you use this option, find changes the access times of directories it searches.

\( \text{depth} \)
The file being evaluated always meets this action criterion. It causes find to take action on entries in a directory before it acts on the directory itself. When you use find to send files to the cpio utility, the \( \text{depth} \) criterion enables cpio to preserve the modification times of directories when you restore files (assuming that you use the \( \text{preserve modification time} \) option to cpio). See the "Discussion" and "Examples" sections under cpio on pages 621 and 622.

\( \text{exec command } \)\;
The file being evaluated meets this action criterion if the command returns a 0 (zero [true]) exit status. You must terminate the command with a quoted semicolon. A pair of braces (\{ \}) within the command represents the name of the file being evaluated. You can use the \( \text{exec} \) action criterion at the end of a group of other criteria to execute the command if the preceding criteria are met. Refer to the following "Discussion" section for more information. See xargs on page 821 for a more efficient way of doing what this option does.

\( \text{follow} \)
(dereference) When this criterion is specified and find encounters a symbolic link, find follows the link.

\( \text{group name} \)
The file being evaluated meets this criterion if it is associated with the group named name. You can use a numeric group ID in place of name.

\( \text{inum } n \)
The file being evaluated meets this criterion if its inode number is \( n \).

\( \text{links } \pm n \)
The file being evaluated meets this criterion if it has \( \pm n \) links.

\( \text{mount} \)
See \( \text{xdev} \).

\( \text{mtime } \pm n \)
(modify time) The file being evaluated meets this criterion if it was last modified \( \pm n \) days ago.

\( \text{name filename} \)
The file being evaluated meets this criterion the pattern filename matches its name. The filename can include wildcard characters (\*, ?, and [ ]) but these characters must be quoted.

\( \text{newer filename} \)
The file being evaluated meets this criterion if it was modified more recently than filename.

\( \text{nogroup} \)
The file being evaluated meets this criterion if it does not belong to a group that is listed in the /etc/group file.

`nouser`

The file being evaluated meets this criterion if it does not belong to a user who is listed in the /etc/passwd file (that is, the user ID of the file does not correspond to a user on the local system).

`ok command`; This action criterion is the same as `exec` but displays each `command` to be executed enclosed in angle brackets and executes the `command` only if it receives a response that starts with a `y` or `Y` from standard input.

`perm [±]mode`

The file being evaluated meets this criterion if it has the access permissions given by `mode`. If `mode` is preceded by a minus sign (\( - \)), the file access permissions must include all the bits in `mode`. If `mode` is preceded by a plus sign (\( + \)), the file access permissions must include at least one of the bits in `mode`. If no plus or minus sign precedes `mode`, the mode of the file must exactly match `mode`. You may use either a symbolic or octal representation for `mode` (see `chmod` on page 604).

`print`

The file being evaluated always meets this action criterion. When evaluation of the `expression` reaches this criterion, `find` displays the pathname of the file it is evaluating. If `print` is the only criterion in the `expression`, `find` displays the names of all files in the `directory-list`. If this criterion appears with other criteria, `find` displays the name only if the preceding criteria are met. If no action criteria appear in the `expression`, `print` is assumed. (Refer to the following "Discussion" and "Notes" sections.)

`size ± n[c|k]`

The file being evaluated meets this criterion if it is the size specified by \( ± n \), measured in 512-byte blocks. Follow \( n \) with the letter \( c \) to measure files in characters or \( k \) to measure files in kilobytes.

`type filetype`

The file being evaluated meets this criterion if its file type is specified by `filetype`. Select a `filetype` from the following list:

- `b` Block special file
- `c` Character special file
- `d` Directory file
- `f` Ordinary file
- `l` Symbolic link
- `p` FIFO (named pipe)
- `s` Socket

`user name`

The file being evaluated meets this criterion if it belongs to the user with the username `name`. You can use a numeric user ID in place of `name`.

`xdev`

The file being evaluated always meets this action criterion. It causes `find` not to search directories in filesystems other than the one specified by `directory-list`. Also `mount`.

Discussion

Assume that \( x \) and \( y \) are criteria. The following command line never tests whether the file meets criterion \( y \) if it does not meet criterion \( x \). Because the criteria are separated by a SPACE (the Boolean AND operator), once `find` determines that criterion \( x \) is not met, the file cannot meet the criteria so `find` does not continue testing. You can read the expression as "(test to see whether) the file meets criterion \( x \) and (SPACE means and) criterion \( y \)."

```
$ find dir x y
```
The next command line tests the file against criterion y if criterion x is not met. The file can still meet the criteria so find continues the evaluation. You can read the expression as “(test to see whether) the file meets criterion x or criterion y.” If the file meets criterion x, find does not evaluate criterion y as there is no need to do so.

```
$ find dir x - or y
```

**Action criteria**

Certain "criteria" do not select files but rather cause find to take action. The action is triggered when find evaluates one of these action criteria. Therefore, the position of an action criterion on the command line—not the result of its evaluation—determines whether find takes the action.

The `print` action criterion causes find to display the pathname of the file it is testing. The following command line displays the names of all files in the dir directory (and all its subdirectories), regardless of whether they meet the criterion x:

```
$ find dir -print x
```

The following command line displays only the names of the files in the dir directory that meet criterion x:

```
$ find dir x -print
```

This common use of `print` after the testing criteria is the default action criterion. The following command line generates the same output as the previous one:

```
$ find dir x
```

**Notes**

You can use the `a` operator between criteria for clarity. This operator is a Boolean AND operator, just as the SPACE is.

**Examples**

The simplest find command has no arguments and lists the files in the working directory and all subdirectories:

```
$ find
...
```

The following command finds the files in the working directory and subdirectories that have filenames beginning with a. The command uses a period to designate the working directory. To prevent the shell from interpreting the `a*` as an ambiguous file reference, it is enclosed within quotation marks.
$ find . -name 'a*' 

The `print` criterion is implicit in the preceding command. If you omit the `directory-list` argument, `find` searches the working directory. The next command performs the same function as the preceding one without explicitly specifying the working directory:

$ find -name 'a*' 

The following command sends a list of selected filenames to the `cpio` utility, which writes them to tape. The first part of the command line ends with a pipe symbol, so the shell expects another command to follow and displays a secondary prompt (`>`) before accepting the rest of the command line. You can read this `find` command as "find, in the root directory and all subdirectories (`/`), ordinary files (`type f`) that have been modified within the past day (`mtime -1`), with the exception of files whose names are suffixed with `.o` (! `name '*.o')." (An object file carries a `.o` suffix and usually does not need to be preserved because it can be re-created from the corresponding source file.)

$ find / -type f - mtime -1 ! -name '*.o' -print | 
> cpio -oB > /dev/ftape 

The following command finds, displays the filenames of, and deletes the files in the working directory and subdirectories named `core` or `junk`:

$ find . \( -name core -o -name junk \) -print -exec rm {} \; 

... 

The parentheses and the semicolon following `exec` are quoted so that the shell does not treat them as special characters. SPACES separate the quoted parentheses from other elements on the command line. Read this `find` command as "find, in the working directory and subdirectories (`.`), files named `core` (`name core`) or (`o`) `junk` (`name junk`) [if a file meets these criteria, continue] and (SPACE) print the name of the file (`print`) and (SPACE) delete the file (`exec rm `{}`)." 

The next shell script uses `find` in conjunction with `grep` to identify files that contain a particular string. This script enables you to look for a file when you remember its contents but cannot remember its filename. The `finder` script locates files in the working directory and subdirectories that contain the string specified on the command line. The `type f` criterion is necessary so that `find` will pass to `grep` only the names of ordinary files, not directory files.

$ cat finder

```
find . -type f -exec grep -l "$1" {} \;
```

$ finder "Executive Meeting"

```
./january/memo.0102
./april/memo.0415
```
When called with the string **Executive Meeting**, `finder` locates two files containing that string: 
`./january/memo.0102` and `./april/memo.0415`. The period (.) in the pathnames represents the working directory; `january` and `april` are subdirectories of the working directory. The `grep` utility with the `-r` option performs the same function as the `finder` script.

The next command looks in two user directories for files that are larger than 100 blocks (`size +100`) and have been accessed only more than five days ago—that is, have not been accessed within the past five days (`atime +5`). This `find` command then asks whether you want to delete the file (`ok rm {}`). You must respond to each query with `y` (for yes) or `n` (for no). The `rm` command works only if you have write and execute access permission to the directory.

```
$ find /home/alex /home/barbara -size +100 -atime +5 -ok rm {} \;
< rm ... /home/alex/notes >? y
< rm ... /home/alex/letter >? n
...
```

In the next example, `/home/alex/memos` is a symbolic link to Jenny's directory named `/home/jenny/memos`. When you use the `-f` option with `find`, the symbolic link is followed, and the contents of that directory are searched.

```
$ ls -l /home/alex

lrwxrwxrwx  1 alex   pubs    17 Aug 19 17:07 memos -> /home/jenny/memos
-rw-r--r--  1 alex   pubs  5119 Aug 19 17:08 report

$ find /home/alex -print

/home/alex
/home/alex/memos
/home/alex/report
/home/alex/.profile

$ find /home/alex -follow -print

/home/alex
/home/alex/memos
/home/alex/memos/memo.817
```
finger: Displays information about users

finger [options] [user-list]

The `finger` utility displays the usernames of users, together with their full names, terminal device numbers, times they logged in, and other information. The `options` control how much information `finger` displays, and the `user-list` specifies which users `finger` displays information about. The `finger` utility can retrieve information from both local and remote systems.

**Arguments**

Without any arguments, `finger` provides a short (`s`) report on users who are logged in on the local system. When you specify a `user-list`, `finger` provides a long (`l`) report on each user in the `user-list`. Names in the `user-list` are not case sensitive.

If the name includes an at sign (`@`), the `finger` utility interprets the name following the `@` as the name of a remote host to contact over the network. If there is also a name in front of the `@` sign, `finger` provides information on that particular user on the remote system.

**Options**

- `l` (**long**) Displays detailed information (the default display when `user-list` is specified).
- `m` (**match**) If a `user-list` is specified, displays entries only for those users whose username matches one of the names in `user-list`. Without this option the `user-list` names match usernames and full names.
- `p` (**no plan, project, or pgpkey**) Does not display the contents of `.plan`, `.project`, and `.pgpkey` files for users. Because these files may contain backslash escape sequences that can change the behavior of the screen, you may not wish to view them. Normally the long listing displays the contents of these files if they exist in the user's home directory.
- `s` (**short**) Provides a short report for each user (the default display when `user-list` is not present).

**Discussion**

The long report provided by the `finger` utility includes the user's username, full name, home directory location, and login shell, plus information about when the user last logged in and how long it has been since the user last typed on the keyboard and read her email. After extracting this information from various system files, the `finger` utility displays the contents of the `~/.plan`, `~/.project`, and `~/.pgpkey` in the user's home directory. It is up to each user to create and maintain these files, which usually provide more information about the user (such as telephone number, postal mail address, schedule, interests, and pgp key).

The short report generated by `finger` is similar to that provided by the `w` utility; it includes the user's username,
his full name, the device number of the user's terminal, the amount of time that has elapsed since the user last typed on the terminal keyboard, the time the user logged in, and the location of the user's terminal. If the user logged in over the network, the name of the remote system is displayed.

Notes

When you specify a network address, the `finger` utility queries a standard network service that runs on the remote system. Although this service is supplied with most Linux systems, some administrators choose not to run it (so as to minimize the load on their systems, to eliminate possible security risks, or simply to maintain privacy). If you try to use `finger` to get information on someone at such a site, the result may be an error message or nothing at all. The remote system determines how much information to share with the local system and in what format. As a result the report displayed for any given system may differ from the examples shown here. See also "finger: Lists Users on the System" on page 64.

A file named `~/.nofinger` causes `finger` to deny the existence of the person whose home directory it appears in. For this subterfuge to work, the `finger` query must originate from a system other than the local host and the `fingerd` daemon must be able to see the `.nofinger` file (generally the home directory must have its execute bit for other users set).

Examples

The first example displays information on the users logged in on the local system:

```
$ finger
Login    Name                 Tty    Idle  Login Time   Office     Office Phone
alex     Alex Watson          tty1   13:29  Jun 25 21:03
hls      Helen Simpson       *pts/1  13:29  Jun 25 21:02 (:0)
jenny    Jenny Chen          pts/2        Jun 26 07:47 (bravo.example.com)
```

The asterisk (*) in front of the name of Helen's terminal (TTY) line indicates that she has blocked others from sending messages directly to her terminal (see `mesg` on page 68). A long report displays the string `messages off` for users who have disabled messages.

The next two examples cause `finger` to contact the remote system named `kudos` over the network for information:

```
$ finger @kudos
[kudos]
Login    Name                 Tty    Idle  Login Time   Office     Office Phone
alex     Alex Watson          tty1   13:29  Jun 25 21:03
hls      Helen Simpson       *pts/1  13:29  Jun 25 21:02 (:0)
jenny    Jenny Chen          pts/2        Jun 26 07:47 (bravo.example.com)
```
alex        Alex Watson        tty1   23:15   Jun 25 11:22
roy        Roy Wong           pts/2            Jun 25 11:22

$ finger watson@kudos

[kudos]

Login: alex                          Name: Alex Watson
Directory: /home/alex               Shell: /bin/zsh

On since Sat Jun 25 11:22 (PDT) on tty1, idle 23:22
Last login Sun Jun 26 06:20 (PDT) on tty2 from speedy
Mail last read Thu Jun 23 08:10 2005 (PDT)

Plan:
For appointments contact Jenny Chen, x1963.

fmt: Formats text very simply

fmt [option] [file-list]

The fmt utility does simple text formatting by attempting to make all nonblank lines nearly the same length.

Arguments

The fmt utility reads the files in file-list and sends a formatted version of their contents to standard output. If you do not specify a filename or if you specify a filename of -, fmt reads from standard input.

Options

- `split-only`  `s`  Splits long lines but does not fill short lines.
- `tagged-paragraph`  `t`  Indents all but the first line of each paragraph.
- `uniform-spacing`  `u`  Changes the formatted output so that one SPACE appears between words and two SPACES appear between sentences.
- `width= n`  `w n`  Changes the output line width to `n` characters. Without this option, fmt keeps output lines close to 75 characters wide. You can also specify this option as `w n`.

Notes
The `fmt` utility works by moving NEWLINE characters. The indentation of lines, as well as the spacing between words, is left intact.

This utility is often used to format text while you are using an editor, such as `vim`. For example, you can format a paragraph with the `vim` editor in command mode by positioning the cursor at the top of the paragraph and then entering `:!fmt 60`. This command replaces the paragraph with the output generated by feeding it through `fmt`, specifying a width of 60 characters. Type `u` immediately if you want to undo the formatting.

**Examples**

The following example shows how `fmt` attempts to make all the lines the same length. The `-w 50` option gives a target line length of 50 characters.

```
$ cat memo
One factor that is important to remember while administering the dietary intake of Charcharodon carcharias is that there is, at least from the point of view of the subject, very little differentiating the prepared morsels being proffered from your digits.

In other words, don't feed the sharks!
```

```
$ fmt -w 50 memo
One factor that is important to remember while administering the dietary intake of Charcharodon carcharias is that there is, at least from the point of view of the subject, very little differentiating the prepared morsels being proffered from your digits.

In other words, don't feed the sharks!
```

The next example demonstrates the `split-only` option. Long lines are broken so that none is longer than 50
The next example demonstrates the split-only option. Long lines are broken so that none is longer than 50 characters; this option prevents fmt from filling short lines.

$ fmt -w 50 --split-only memo

One factor that is important to remember while administering the dietary intake of Charcharodon carcharias is that there is, at least from the point of view of the subject, very little differentiating the prepared morsels being proffered from your digits.

In other words, don't feed the sharks!

fsck: Checks and repairs a filesystem

fsck [options] [filesystem-list]

The fsck utility verifies the integrity of a filesystem and reports on and optionally repairs problems it finds. It is a front end for filesystem checkers, each specific to a filesystem type.

Arguments

Without the \[A option and with no filesystem-list, fsck checks the filesystems listed in the /etc/fstab file one at a time (serially). With the \[A option and with no filesystem-list, fsck checks all the filesystems listed in the /etc/fstab file in parallel if possible. See the \[s option for a discussion of checking filesystems in parallel.

The filesystem-list specifies the filesystems to be checked. It can either specify the name of the device that holds the filesystem (for example, /dev/hda2) or, if the filesystem appears in /etc/fstab, specify the mount point (for example, /usr2) for the filesystem. The filesystem-list can also specify the label for the filesystem from /etc/fstab (for example, LABEL=home).

Options

When you run fsck, you can specify both global options and options specific to the filesystem type that fsck is checking (for example, ext2, ext3, msdos, reiserfs). Global options must precede type-specific options.
Global Options

[A (all)] Process all the filesystems listed in the /etc/fstab file, in parallel if possible. See the [s] option for a discussion of checking filesystems in parallel. Do not specify a filesystem-list when you use this option; you can specify filesystem types to be checked with the [t] option. Use this option with the [a], [p], or [in] option so that fsck does not attempt to process filesystems in parallel interactively (in which case you would have no way of responding to its multiple prompts).

[N (no)] Assumes a no response to any questions that arise while processing a filesystem. This option generates the messages you would normally see but causes fsck to take no action.

[R (root-skip)] With the [A] option does not check the root filesystem. Useful when the system boots, because the root filesystem may be mounted with read-write access.

[s (serial)] Causes fsck to process filesystems one at a time. Without this option, fsck processes multiple filesystems that reside on separate physical disk drives in parallel. Parallel processing enables fsck to process multiple filesystems more quickly. This option is required if you want to process filesystems interactively. See the [a], [p], or [in] option to turn off interactive processing.

[fstype (filesystem type)] A comma-separated list that specifies the filesystem type(s) to process. With the [A] option fsck processes all the filesystems in /etc/fstab that are of type fstype. Common filesystem types are ext2, ext3, msdos, and reiserfs. You do not typically check remote NFS filesystems.

[T (title)] Causes fsck not to display its title.

[V (verbose)] Displays more output, including filesystem type-specific commands.

Filesystem Type-Specific Options

The following command lists the filesystem checking utilities available on the local system. Files with the same inode numbers are linked (page 99).

$ ls -i /sbin/*fsck*

63801 /sbin/dosfsck  63856 /sbin/fsck.cramfs  63801 /sbin/fsck.msdos
63763 /sbin/e2fsck   63763 /sbin/fsck.ext2    63801 /sbin/fsck.vfat
63780 /sbin/fsck     63763 /sbin/fsck.ext3

Review the man page or give the pathname of the filesystem checking utility to determine which options the utility accepts:

$ /sbin/fsck.ext3

Usage: /sbin/fsck.ext3 [-panyrdstDFSV] [-b superblock] [-B blocksize]
       [-I inode_buffer_blocks] [-P process_inode_size]
       [-l|-L bad_blocks_file] [-C fd] [-j ext-journal]
       [-E extended-options] device
Emergency help:

- **p** Automatic repair (no questions)
- **n** Make no changes to the filesystem
- **y** Assume "yes" to all questions
- **c** Check for bad blocks and add them to the badblock list
- **f** Force checking even if filesystem is marked clean

The following options apply to many filesystem types, including **ext2** and **ext3**:

- **a** *(automatic)* Same as the **p** option; kept for backward compatibility.
- **f** *(force)* Forces **fsck** to check filesystems even if they are **clean**. A clean filesystem is one that was just successfully checked with **fsck** or was successfully unmounted and has not been mounted since. Clean filesystems are skipped by **fsck**, greatly speeding up system booting under normal conditions. For information on setting up periodic, automatic filesystem checking on **ext2** and **ext3** filesystems, see **tune2fs** on page 808.
- **p** *(preen)* Attempts to repair all minor inconsistencies it finds when processing a filesystem. If any problems are not repaired, **fsck** terminates with a nonzero exit status. This option runs **fsck** in batch mode so that it does not ask whether to correct each problem it finds. The **p** option is commonly used with the **A** option when checking filesystems while booting Linux.
- **r** *(interactive)* Asks whether to correct or ignore each problem that is found. For many filesystem types, this behavior is the default.
- **y** *(yes)* Assumes a yes response to any questions that **fsck** asks while processing a filesystem. Use this option with caution as it gives **fsck** free reign to do what it thinks is best to clean up a filesystem.

Notes

When a filesystem is consistent, **fsck** displays a report such as the following:

```bash
# /sbin/fsck -f /dev/hda1
fsck 1.35 (28-Feb-2004)
e2fsck 1.35 (28-Feb-2004)
Pass 1: Checking inodes, blocks, and sizes
Pass 2: Checking directory structure
Pass 3: Checking directory connectivity
```
Pass 4: Checking reference counts

Pass 5: Checking group summary information

/boot: 71/26104 files (15.5% non-contiguous), 37257/104391 blocks

Interactive mode

You can run `fsck` either interactively or in batch mode. For many filesystems, unless you use one of the `a`, `p`, `y`, or `n` options, `fsck` runs in interactive mode. In interactive mode, if `fsck` finds a problem with a filesystem, it reports the problem and allows you to choose whether to repair or ignore it. If you repair a problem you may lose some data; however, that is often the most reasonable alternative.

Although it is technically feasible to repair files that are damaged and that `fsck` says you should remove, this action is usually not practical. The best insurance against significant loss of data is frequent backups.

Order of checking

The `fsck` utility looks at the sixth column in the `/etc/fstab` file to determine if, and in what order, it should check filesystems. A 0 (zero) in this position indicates that the filesystem should not be checked. A 1 (one) indicates that it should be checked first and is usually reserved for the root filesystem. A 2 indicates that the filesystem should be checked after those marked with a 1.

`fsck` is a front end

Similar to `mkfs` (page 725), `fsck` is a front end that calls other utilities to handle various types of filesystems. For example, `fsck` calls `e2fsck` to check the widely used `ext2` and `ext3` filesystems. (Refer to the `e2fsck man` page for more information.) Other utilities that `fsck` calls are typically named `fsck.type`, where `type` is the filesystem type. By splitting `fsck` in this manner, filesystem developers can provide programs to check their filesystems without affecting the development of other filesystems or changing how system administrators use `fsck`.

Boot time

Run `fsck` on filesystems that are unmounted or mounted readonly. When Linux is booting, the root filesystem is first mounted readonly to allow it to be processed by `fsck`. If `fsck` finds no problems with the root filesystem, it is then remounted (using the `remount` option to the `mount` utility) read-write and `fsck` is typically run with the `-A`, `-R`, and `-p` options.

lost+found

When it encounters a file that has lost its link to its filename, `fsck` asks whether to reconnect it. If you choose to reconnect it, the file is put in a directory named `lost+found` in the root directory of the filesystem that the file was found in. The reconnected file is given its inode number as a name. For `fsck` to restore files in this way, a `lost+found` directory must be in the root directory of each filesystem. For example, if a system uses the `/`, `/usr`, and
lost+found directories must be in the root directory of each filesystem. For example, if a system uses the /
/usr, and /tmp filesystems, you should have these three lost+found directories: /lost+found, /usr/lost+found, and /tmp/lost+found. Each of the lost+found directories must have unused entries that fsck can use to store the inode numbers for files that have lost their links. When you create an ext2 and ext3 filesystem using mkfs (page 725), a lost+found directory with the required unused entries is created automatically. Alternatively, you can use the mklost+found utility to create this directory in ext2 and ext3 filesystems if needed. On other types of filesystems you can create the unused entries by adding many files to the directory and then removing them. Try using touch (page 801) to create 500 entries in the lost+found directory and then using rm to delete them.

Messages

Table V-14 lists fsck’s common messages. In general fsck suggests the most logical way of dealing with a problem in the file structure. Unless you have information that suggests another response, respond to the prompts with yes. Use the system backup tapes or disks to restore data that is lost as a result of this process.

<table>
<thead>
<tr>
<th>Phase (message)</th>
<th>What fsck checks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase 1 - Check inodes, blocks, and sizes</td>
<td>Checks inode information.</td>
</tr>
<tr>
<td>Phase 2 - Check directory structures</td>
<td>Looks for directories that point to bad inodes that fsck found in Phase 1.</td>
</tr>
<tr>
<td>Phase 3 - Check directory connectivity</td>
<td>Looks for unreferenced directories and a nonexistent or full lost+found directory.</td>
</tr>
<tr>
<td>Phase 4 - Check reference counts</td>
<td>Checks for unreferenced files, a nonexistent or full lost+found directory, bad link counts, bad blocks, duplicated blocks, and incorrect inode counts.</td>
</tr>
<tr>
<td>Phase 5 - Check group summary information</td>
<td>Checks whether the free list and other filesystem structures are OK. If any problems are found with the free list, Phase 6 is run.</td>
</tr>
<tr>
<td>Phase 6 - Salvage free list</td>
<td>If Phase 5 found any problems with the free list, Phase 6 fixes them.</td>
</tr>
</tbody>
</table>

Cleanup

Once it has repaired the filesystem, fsck informs you about the status of the filesystem. The fsck utility displays the following message after it repairs a filesystem:

*****File System Was Modified*****

On ext2 and ext3 filesystems, fsck displays the following message when it has finished checking a filesystem:

filesys: used/maximum files (percent non-contiguous), used/maximum blocks

This message tells you how many files and disk blocks are in use as well as how many files and disk blocks the filesystem can hold. The percent non-contiguous tells you how fragmented the disk is.

ftp: Transfers files over a network

ftp [options] [remote-system]
The \texttt{ftp} utility is a user interface to the standard File Transfer Protocol (FTP), which transfers files between systems that can communicate over a network. To establish an FTP connection, you must have an account (personal, guest, or anonymous) on the remote system.

**security: Use FTP only to download public information**

FTP is not a secure protocol. The \texttt{ftp} utility sends your password over the network as cleartext, which is not a secure practice. You can use \texttt{scp} (page 758) for many FTP functions other than allowing anonymous users to download information. Because \texttt{scp} uses an encrypted connection, user passwords and data cannot be sniffed.

**Arguments**

The \texttt{remote-system} is the name or network address of the server, running an \texttt{ftpd} daemon, that you want to exchange files with.

**Options**

- \texttt{\textbackslash i (interactive)} (Turns off prompts during file transfers with \texttt{mget} and \texttt{mput}. See also \texttt{prompt}.
- \texttt{\textbackslash n (no automatic login)} (Disables automatic logins.
- \texttt{\textbackslash v (verbose)} (Tells you more about how \texttt{ftp} is working. Displays responses from the \texttt{remote-system} and reports transfer times and speeds.

**Discussion**

The \texttt{ftp} utility is interactive. After you start it, \texttt{ftp} prompts you to enter commands to set parameters and transfer files. You can use a number of commands in response to the \texttt{ftp>} prompt; following are some of the more common ones.

\begin{itemize}
  \item \texttt{\textbackslash ![ command ]} (Escapes to (spawns) a shell on the local system (use CONTROL-D or \texttt{exit} to return to \texttt{ftp} when you are finished using the local shell). Follow the exclamation point with a command to execute that command only; \texttt{ftp} returns you to the \texttt{ftp>} prompt when the command completes executing. Because the shell that \texttt{ftp} spawns with this command is a child of the shell that is running \texttt{ftp}, no changes you make in this shell are preserved when you return to \texttt{ftp}. Specifically, when you want to copy files to a local directory other than the directory that you started \texttt{ftp} from, you need to use the \texttt{ftp lcd} command to change the local working directory: Issuing a \texttt{cd} command in the spawned shell will not make the change you desire. See "\texttt{lcd (local cd)}" on page 676 for an example.
  \item \texttt{ascii} (Sets the file transfer type to ASCII. Allows you to transfer text files from systems that end lines with a RETURN/LINEFEED combination and automatically strip off the RETURN. This type of transfer is useful when the remote computer is a DOS or MS Windows machine. The \texttt{cr} command must be ON for \texttt{ascii} to work.
  \item \texttt{binary} (Sets the file transfer type to binary. Allows you to transfer files that contain non-ASCII (unprintable) characters correctly. This option also works for ASCII files that do not require changes to the ends of lines.
  \item \texttt{bye} (Closes the connection to a remote system and terminates \texttt{ftp}. Same as \texttt{quit}.
  \item \texttt{cd remote-directory} (Changes to the working directory named \texttt{remote-directory} on the remote system.
\end{itemize}
close     Closes the connection with the remote system without exiting from **ftp**.

**cr**     Toggles RETURN stripping when you retrieve files in ASCII mode. See **ascii**.

**dir**    Displays a listing of the directory named **directory** from the remote system. When you do not specify **directory**, the working directory is displayed. When you specify **file**, the listing is saved on the local system in a file named **file**.

**get**    Copies **remote-file** to the local system under the name **local-file**. Without **local-file**, **ftp** uses **remote-file** as the filename on the local system. The **remote-file** and **local-file** names can be pathnames.

**glob**   Toggles filename expansion for **mget** and **mput** commands and displays the current state (Globbing on or Globbing off).

**help**   Displays a list of commands recognized by the **ftp** utility on the local system.

**lcd**    (local change directory) Changes the working directory on the local system to **local_directory**. Without an argument changes the working directory on the local system to your home directory (just as **cd** does without an argument).

**ls**     Similar to **dir** but produces a more concise listing on some remote computers. When you specify **file**, the listing is saved on the local system in a file named **file**.

**mget**   (multiple get) Unlike the **get** command, the **mget** command allows you to retrieve multiple files from the remote system. You can name the remote files literally or use wildcards (see **glob**). See also **prompt**.

**mput**   (multiple put) The **mput** command allows you to copy multiple files from the local system to the remote system. You can name the local files literally or use wildcards (see **glob**). See also **prompt**.

open      Interactively specifies the name of the remote system. This command is useful if you did not specify a remote system on the command line or if the attempt to connect to the system failed.

**passive** Toggles between active (PORT—the default) and passive (PASV) transfer modes and displays the transfer mode. See "Passive versus active connections" under "Notes."

prompt    When using **mget** or **mput** to receive or send multiple files, **ftp** asks for verification (by default) before transferring each file. This command toggles that behavior and displays the current state (Interactive mode off or Interactive mode on).

put        Copies **local-file** to the remote system under the name **remote-file**. Without **remote-file**, **ftp** uses **local-file** as the filename on the remote system. The **remote-file** and **local-file** names can be pathnames.

**pwd**    Causes **ftp** to display the pathname of the remote working directory. Use !**pwd** to display the name of the local working directory.

**quit**   Quits the **ftp** session. Same as **bye**.

**user**   If the **ftp** utility did not log you in automatically, you can specify your account name as **username**. Without **username**, **ftp** prompts you for your username.

**Notes**

A Linux system running **ftp** can exchange files with any of the many operating systems that support the FTP protocol. Many sites offer archives of free information on an FTP server, although many of these are merely
alternatives to an easier-to-access Web site (for example, ftp://ftp.ibiblio.org/pub/Linux and http://www.ibiblio.org/pub/Linux). Most browsers can connect to and download files from FTP servers.

The `ftp` utility makes no assumptions about filesystem naming or structure because you can use `ftp` to exchange files with non-UNIX/Linux systems (whose filename conventions may be different).

**Anonymous FTP**

Many systems—most notably those from which you can download free software—allow you to log in as anonymous. Most systems that support anonymous logins accept the name `ftp` as an easier-to-spell and quicker-to-enter synonym for anonymous. An anonymous user is usually restricted to a portion of a filesystem set aside to hold files that are to be shared with remote users. When you log in as an anonymous user, the server prompts you to enter a password. Although any password may be accepted, by convention you are expected to supply your email address. Many systems that permit anonymous access store interesting files in the `pub` directory.

**Passive versus active connections**

A client can ask an FTP server to establish either a PASV (passive—the default) or a PORT (active) connection for data transfer. Some servers are limited to one type of connection. The difference between a passive and an active FTP connection lies in whether the client or server initiates the data connection. In passive mode, the client initiates the data connection to the server (on port 20 by default); in active mode, the server initiates the data connection (there is no default port). Neither type of connection is inherently more secure. Passive connections are more common because a client behind a `NAT` (page 889) firewall can connect to a passive server and because it is simpler to program a scalable passive server.

**Automatic login**

You can store server-specific FTP username and password information so that you do not have to enter it each time you visit an FTP site. Each line of the `~/.netrc` file identifies a server. When you connect to an FTP server, `ftp` reads `~/.netrc` to determine whether you have an automatic login set up for that server. The format of a line in `~/.netrc` is

```
machine server login username password passwd
```

where `server` is the name of the server, `username` is your username, and `password` is your password on `server`. Replace `machine` with `default` on the last line of the file to specify a username and password for systems not listed in `~/.netrc`. The `default` line is useful for logging in on anonymous servers. A sample `~/.netrc` file follows:

```
$ cat ~/.netrc

machine bravo login alex password mypassword

default login anonymous password alex@example.com
```

Protect the account information in `~/.netrc` by making it readable by only the user whose home directory it appears in. Refer to the `netrc man` page for more information.
Examples

Following are two `ftp` sessions wherein Alex transfers files from and to an FTP server named `bravo`. When Alex gives the command `ftp bravo`, the local `ftp` client connects to the server, which asks for a username and password. Because he is logged in on his local system as `alex`, `ftp` suggests that he log in on `bravo` as `alex`. To log in as `alex`, he could just press RETURN. His username on `bravo` is `watson`, however, so he types `watson` in response to the `Name (bravo:alex)`: prompt. Alex responds to the `Password:` prompt with his normal system password, and the FTP server greets him and informs him that it is Using binary mode to transfer files. With `ftp` in binary mode, Alex can transfer ASCII and binary files.

Connect and log in

```sh
$ ftp bravo
Connected to bravo.
220 (vsFTPd 1.2.0)
530 Please login with USER and PASS.
530 Please login with USER and PASS.
KERBEROS_V4 rejected as an authentication type
Name (bravo:alex): watson
331 Please specify the password.
Password:
230 Login successful.
Remote system type is UNIX.
Using binary mode to transfer files.
```

After logging in, Alex uses the `ftp ls` command to display the contents of his remote working directory, which is his home directory on `bravo`. Then he `cds` to the `memos` directory and displays the files there.
ftp> ls
227 Entering Passive Mode (192,168,0,6,79,105)
150 Here comes the directory listing.

    drwxr-xr-x    2 500      500          4096 Oct 10 23:52 expenses
    drwxr-xr-x    2 500      500          4096 Oct 10 23:59 memos
    drwxrwxr-x   22 500      500          4096 Oct 10 23:32 tech
226 Directory send OK.

ftp> cd memos
250 Directory successfully changed.

ftp> ls
227 Entering Passive Mode (192,168,0,6,114,210)
150 Here comes the directory listing.

    -rw-r--r--    1 500      500          4770 Oct 10 23:58 memo.0514
    -rw-r--r--    1 500      500          7134 Oct 10 23:58 memo.0628
    -rw-r--r--    1 500      500          9453 Oct 10 23:58 memo.0905
    -rw-r--r--    1 500      500          3466 Oct 10 23:59 memo.0921
    -rw-r--r--    1 500      500          1945 Oct 10 23:59 memo.1102
226 Directory send OK.

Next Alex uses the **ftp get** command to copy **memo.1102** from the server to the local system. Binary mode ensures that he will get a good copy of the file regardless of whether it is binary or ASCII. The server confirms that the file was copied successfully and notes the size of the file and the time it took to copy. Alex then copies the local file **memo.1114** to the remote system. The file is copied into his remote working directory, **memos**.

get and put

ftp> get memo.1102
local: memo.1102 remote: memo.1102
1945 bytes received in 7.1e-05 secs (2.7e+04 Kbytes/sec)

ftp> put memo.1114
local: memo.1114 remote: memo.1114
227 Entering Passive Mode (192,168,0,6,174,97)
150 Ok to send data.
226 File receive OK.
1945 bytes sent in 2.8e-05 secs (6.8e+04 Kbytes/sec)

After a while Alex decides he wants to copy all the files in the memo directory on bravo to a new directory on his local system. He gives an ls command to make sure he is going to copy the right files, but ftp has timed out. Instead of exiting from ftp and giving another ftp command from the shell, Alex gives ftp an open bravo command to reconnect to the server. After logging in, he uses the ftp cd command to change directories to memos on the server.

Timeout and open

ftp> ls
421 Timeout.
Passive mode refused.
ftp> open bravo
Connected to bravo (192.168.0.6).
220 (vsFTPD 1.1.3)
...
ftp> cd memos
250 Directory successfully changed.
At this point, Alex realizes he has not created the new directory to hold the files he wants to download. Giving an `ftp mkdir` command would create a new directory on the server, but Alex wants a new directory on the local system. He uses an exclamation point (!) followed by a `mkdir memos.hold` command to invoke a shell and run `mkdir` on the local system, creating a directory named `memos.hold` in his working directory on the local system. (You can display the name of your working directory on the local system with `!pwd`). Next, because he wants to copy files from the server to the `memos.hold` directory on his local system, he has to change his working directory on the local system. Giving the command `!cd memos.hold` will not accomplish what Alex wants to do because the exclamation point spawns a new shell on the local system and the `cd` command would be effective only in the new shell, which is not the shell that `ftp` is running under. For this situation, `ftp` provides the `lcd (local cd)` command, which changes the working directory for `ftp` and reports on the new local working directory.

```bash
ftp> !mkdir memos.hold
ftp> lcd memos.hold
Local directory now /home/alex/memos.hold
```

Alex uses the `ftp mget` (multiple get) command followed by the asterisk (*) wildcard to copy all the files from the remote `memos` directory to the `memos.hold` directory on the local system. When `ftp` prompts him for the first file, he realizes that he forgot to turn off prompts, responds with `n`, and presses `CONTROL-C` to stop copying files in response to the second prompt. The server checks whether he wants to continue with his `mget` command.

```bash
ftp> mget *
mget memo.0514? n
mget memo.0628? CONTROL-C
Continue with mget? n
```

Next Alex gives the `ftp prompt` command, which toggles the prompt action (turns it off if it is on and turns it on if it is off). Now when he gives an `mget *` command, `ftp` copies all the files without prompting him.

After getting the files he wants, Alex gives a `quit` command to close the connection with the server, exit from `ftp`, and return to the local shell prompt.

```bash
ftp> quit
```

`mget and prompt`
ftp> mget *
local: memo.0514 remote: memo.0514

227 Entering Passive Mode (192,168,0,6,53,55)

ftp> quit

221 Goodbye.

gcc: Compiles C and C++ programs

gcc [options] file-list [larg]
g++ [options] file-list [larg]

The Linux operating system uses the GNU C compiler, gcc, to preprocess, compile, assemble, and link C language source files. The same compiler with a different front end, g++, processes C++ source code. The gcc and g++ compilers can also assemble and link assembly language source files, link object files only, or build object files for use in shared libraries.

These compilers take input from files you specify on the command line. Unless you use the -o option, they store the executable program in a.out.

The gcc and g++ compilers are part of GCC, the GNU Compiler Collection, which includes front ends for C, C++, Objective C, Fortran, Java, and Ada as well as libraries for these languages. Go to gcc.gnu.org for more information.

**tip:** gcc and g++
Although this section specifies the gcc compiler, most of it applies to g++ as well.

Arguments

The **file-list** is a list of the pathnames of the files that gcc is to process.

Options

Without any options gcc accepts C language source files, assembly language files, object files, and other files described in Table V-15 on page 681. The gcc utility preprocesses, compiles, assembles, and links these files as appropriate, producing an executable file named **a.out**. If gcc is used to create object files without linking them to produce an executable file, each object file is named by adding the extension **.o** to the basename of the corresponding source file. If gcc is used to create an executable file, it deletes the object files after linking.

<table>
<thead>
<tr>
<th>Extension</th>
<th>Type of file</th>
</tr>
</thead>
<tbody>
<tr>
<td>.a</td>
<td>Library of object modules</td>
</tr>
<tr>
<td>.c</td>
<td>C language source file</td>
</tr>
<tr>
<td>.C, .cc, or .cxx</td>
<td>C++ language source file</td>
</tr>
<tr>
<td>.i</td>
<td>Preprocessed C language source file</td>
</tr>
<tr>
<td>.ii</td>
<td>Preprocessed C++ language source file</td>
</tr>
<tr>
<td>.o</td>
<td>Object file</td>
</tr>
<tr>
<td>.s</td>
<td>Assembly language source file</td>
</tr>
<tr>
<td>.S</td>
<td>Assembly language source file that needs preprocessing</td>
</tr>
</tbody>
</table>

Some of the most commonly used options are listed here. When certain filename extensions are associated with an option, you can assume that the extension is added to the basename of the source file.

- **c** ( compile ) Suppresses the linking step of compilation. Compiles and/or assembles source code files and leaves the object code in files with the extension **.o**.

- **D name [= value ]**
  
  Usually **#define** preprocessor directives are given in header, or include, files. You can use this option to define symbolic names on the command line instead. For example, **#DLinux** is equivalent to having the line **#define Linux** in an include file, and **#DMACH=i586** is the same as **#define MACH i586**.

- **E** ( everything ) On source code files, suppresses all steps of compilation except preprocessing and writes the result to standard output. By convention the extension **.i** is used for preprocessed C source and **.ii** for preprocessed C++ source.

- **fpic**
  
  Causes gcc to produce position-independent code, which is suitable for installing into a shared library.

- **fwritable-strings**
  
  By default the GNU C compiler places string constants into protected memory, where they cannot be changed. Some (usually older) programs assume that you can modify string constants. This option changes the behavior of gcc so string constants can be modified.

- **g** ( gdb ) Embeds diagnostic information in the object files. This information is used by symbolic debuggers, such as gdb (page 412). Although it is necessary only if you later use a debugger, it is a good practice to
include this option as a matter of course.

**I directory**

Looks for include files in directory before looking in the standard locations. Give this option multiple times to look in more than one directory.

**l arg**

(Lowercase "l") Searches the directories /lib and /usr/lib for a library file named lib arg .a. If the file is found, gcc then searches this library for any required functions. Replace arg with the name of the library you want to search. For example, the lm option normally links the standard math library libm.a. The position of this option is significant: It generally needs to go at the end of the command line but can be repeated multiple times to search different libraries. Libraries are searched in the order in which they appear on the command line. The linker uses the library only to resolve undefined symbols from modules that precede the library option on the command line. You can add other library paths to search for lib arg .a using the L option.

**L directory**

Adds directory to the list of directories to search for libraries given with the l option. Directories that are added to the list with L are searched before looking in the standard locations for libraries.

**o file**

(output) Names the executable program that results from linking file instead of a.out.

**O n**

(optimize) Attempts to improve (optimize) the object code produced by the compiler. The value of n may be 0, 1, 2, or 3 (or 06 if you are compiling code for the Linux kernel). The default value of n is 1. Larger values of n result in better optimization but may increase both the size of the object file and the time it takes gcc to run. Using O0 turns off optimization. Many related options control precisely the types of optimizations attempted by gcc when you use O. Refer to the gcc info page for details.

**pedantic**

The C language accepted by the GNU C compiler includes features that are not part of the ANSI standard for the C language. Using this option forces gcc to reject these language extensions and accept only standard C programming language features.

**Q**

Displays the names of functions as gcc compiles them. Also displays statistics about each pass.

**S**

(suppress) Suppresses the assembling and linking steps of compilation on source code files. The resulting assembly language files have .s filename extensions.

**traditional**

Causes gcc to accept only C programming language features that existed in the traditional Kernighan and Ritchie C programming language. This option allows you to compile correctly older programs written using the traditional C language that existed before the ANSI standard C language was defined.

**Wall**

Causes gcc to warn you about questionable code in the source code files. Many related options control warning messages more precisely. See page 408.

**Notes**

The preceding list of options represents only a small fraction of the full set of options available with the GNU C compiler. See the gcc info page for a complete list.

See "Programming in C" on page 388 for more information about using the gcc compiler.

Although the o option is generally used to specify a filename to store object code, this option also allows you to name files resulting from other compilation steps. In the following example, the o option causes the assembly language produced by the gcc command to be stored in the file acode instead of pgm.s, the default:
$ gcc -S -o acode pgm.c

The lint utility found in many UNIX systems is not available on Linux. However, the Wall option (page 408) performs many of the same checks and can be used in place of lint.

The conventions used by the C compiler for assigning filename extensions are summarized in Table V-15.

Examples

The first example compiles, assembles, and links a single C program, compute.c. The executable output is put in a.out. The gcc utility deletes the object file.

$ gcc compute.c

The next example compiles the same program using the C optimizer (-O option). It assembles and links the optimized code. The -o option causes gcc to put the executable output in compute.

$ gcc -O -o compute compute.c

Next a C source file, an assembly language file, and an object file are compiled, assembled, and linked. The executable output goes in progo.

$ gcc -o progo procom.c profast.s proout.o

In the next example, gcc searches the standard math library stored in /lib/libm.a when it is linking the himath program and puts the executable output in a.out:

$ gcc himath.c -lm

In the following example, the C compiler compiles topo.c with options that check the code for questionable source code practices (Wall option) and violations of the ANSI C standard (pedantic option). The g option embeds debugging support in the executable file, which is saved in topo with the -o topo option. Full optimization is enabled with the -O3 option.

The warnings produced by the C compiler are sent to standard output. Here the first and last warnings result from the pedantic option; the other warnings result from the Wall option:

$ gcc -Wall -g -O3 -pedantic -o topo topo.c

In file included from topo.c:2:
/usr/include/ctype.h:65: warning: comma at end of enumerator list

Topo.c:13: warning: return-type defaults to 'int'

Topo.c: In function 'main':

$ gcc -Wall -g -O3 -pedantic -o topo topo.c

In file included from topo.c:2:
/usr/include/ctype.h:65: warning: comma at end of enumerator list

Topo.c:13: warning: return-type defaults to 'int'

Topo.c: In function 'main':
When compiling programs that use the X11 include files and libraries, you may need to use the `-I` and `-L` options to tell `gcc` where to locate those include files and libraries. The next example uses those options and instructs `gcc` to link the program with the basic X11 library:

```
$ gcc -I/usr/X11R6/include plot.c -L/usr/X11R6/lib -lX11
```

### grep: Searches for a pattern in files

```
grep [options] pattern [file-list]
```

The `grep` utility searches one or more files, line by line, for a **pattern**, which can be a simple string or another form of a regular expression. The `grep` utility takes various actions, specified by options, each time it finds a line that contains a match for the **pattern**. This utility takes its input from files you specify on the command line or from standard input.

#### Arguments

The **pattern** is a regular expression, as defined in Appendix A. You must quote regular expressions that contain special characters, SPACE s, or TAB s. An easy way to quote these characters is to enclose the entire expression within single quotation marks.

The **file-list** is a list of the pathnames of ordinary files that `grep` searches. With the `-r` option, **file-list** may contain directories whose contents are searched.

#### Options

Without any options `grep` sends lines that contain a match for **pattern** to standard output. When you specify more than one file on the command line, `grep` precedes each line that it displays with the name of the file that it came from followed by a colon.

**Major Options**

You can use only one of the following three options at a time. Normally you do not need to use any, because `grep` defaults to `-G`, which is regular `grep`.

- `-E` (**extended**) Interprets **pattern** as an extended regular expression (page 836). The command `grep -E` is the same as `egrep`. See "Notes" later in this section.
- `-F` (**fixed**) Interprets **pattern** as a fixed string of characters. The command `grep -F` is the same as `fgrep`.
- `-G` (**grep**) Interprets **pattern** as a basic regular expression. This is the default major option if none is specified.
Other Options

Accepts the common options described on page 587.

- `c` Displays only the number of lines that contain a match in each file.
- `C n` Displays `n` lines of context around each matching line.
- `f file` Reads `file`, which contains one pattern per line, and finds lines in the input that match each of the patterns.
- `h` Does not display the filename at the beginning of each line when searching through multiple files.
- `i` Causes lowercase letters in the pattern to match uppercase letters in the file, and vice versa. Use this option when you are searching for a word that may be at the beginning of a sentence (that is, may or may not start with an uppercase letter).
- `l` (lowercase "l") Displays only the name of each file that contains one or more matches. A filename is displayed only once, even if the file contains more than one match.
- `m n` Stops reading each file, or standard input, after displaying `n` lines containing matches.
- `n` Precedes each line by its line number in the file. The file does not need to contain line numbers.
- `q` Does not write anything to standard output; only sets the exit code.
- `r or R` Recursively descends directories in `file-list` and processes files within these directories.
- `s` (silent) Does not display an error message if a file in `file-list` does not exist or is not readable.
- `v` Causes lines not containing a match to satisfy the search. When you use this option by itself, `grep` displays all lines that do not contain a match for the pattern.
- `w` With this option, the pattern must match a whole word. This option is helpful if you are searching for a specific word that may also appear as a substring of another word in the file.
- `x` The pattern matches whole lines only.

Notes

The `grep` utility returns an exit status of 0 if it finds a match, 1 if it does not find a match, and 2 if the file is not accessible or there is a syntax error.

`egrep` and `fgrep`

Two utilities perform functions similar to that of `grep`. The `egrep` utility (same as `grep E`) allows you to use extended regular expressions (page 836), which include a different set of special characters than basic regular expressions (page 834). The `fgrep` utility (same as `grep F`) is fast and compact but processes only simple strings, not regular expressions.
Examples

The following examples assume that the working directory contains three files: testa, testb, and testc:

File testa     File testb     File testc

aaabb         aaaaa          AAAAA
bbbcc         bbbbb          BBBBB
ff-ff         cccccc          CCCCC
cccdd         dddddd          DDDDD
dddaa
dddaa

The grep utility can search for a pattern that is a simple string of characters. The following command line searches testa and displays each line containing the string bb:

$ grep bb testa

aaabb

bbbcc

The v option reverses the sense of the test. The following example displays the lines in testa without bb:

$ grep -v bb testa

ff-ff

ccddd

dddad

The n option displays the line number of each displayed line:

$ grep -n bb testa

1:aaabb

2:bbbcc

The grep utility can search through more than one file. Here grep searches through each file in the working
The grep utility can search through more than one file. Here grep searches through each file in the working directory. The name of the file containing the string precedes each line of output.

```
$ grep bb *
  testa:aaabb
  testa:bbbcc
  testb:bbbbbb
```

When the search for the string `bb` is done with the `-w` option, grep produces no output because none of the files contains the string `bb` as a separate word:

```
$ grep -w bb *
$
```

The search that `grep` performs is case sensitive. Because the previous examples specified lowercase `bb`, grep did not find the uppercase string `BBBBB` in `testc`. The `-i` option causes both uppercase and lowercase letters to match either case of letter in the pattern:

```
$ grep -i bb *
  testa:aaabb
  testa:bbbcc
  testb:bbbbbb
  testc:BBBBB
$ grep -i BB *
  testa:aaabb
  testa:bbbcc
  testb:bbbbbb
  testc:BBBBB
```

The `-c` option displays the number of lines in each file that contain a match:

```
$ grep -c bb *
  testa:2
```
The `f` option finds matches for each pattern in a file of patterns. The next example shows `gfile`, which holds two patterns, one per line, and `grep` searching for matches to the patterns in `gfile`:

```
$ cat gfile
aaa
bbb
$ grep -f gfile test*

testa:aaabb
testa:bbbcc
testb:aaaaa
testb:bbbb
```

The following command line displays from `text2` lines that contain a string of characters starting with `st`, followed by zero or more characters (`*` represents zero or more characters in a regular expression; see Appendix A), and ending in `ing`:

```
$ grep 'st.*ing' text2
...
```

The `^` regular expression, which matches the beginning of a line, can be used alone to match every line in a file. Together with the `-n` option, `^` can be used to display the lines in a file, preceded by their line numbers:

```
$ grep -n '^' testa
1:aaabb
2:bbbcc
3:ff-ff
4:cccdd
5:dddaa
```

The next command line counts the number of times `#include` statements appear in C source files in the working
The next command line counts the number of times #include statements appear in C source files in the working directory. The h option causes grep to suppress the filenames from its output. The input to sort is all lines from *.c that match #include. The output from sort is an ordered list of lines that contains many duplicates. When uniq with the c option processes this sorted list, it outputs repeated lines only once, along with a count of the number of repetitions in its input.

```bash
$ grep -h '#include' *.c | sort | uniq -c
9 #include "buff.h"
2 #include "poly.h"
1 #include "screen.h"
6 #include "window.h"
2 #include "x2.h"
2 #include "x3.h"
2 #include <math.h>
3 #include <stdio.h>
```

The final command calls the vim editor with a list of files in the working directory that contain the string Sampson. The $(...) command substitution construct (page 329) causes the shell to execute grep in place and supply vim with a list of filenames that you want to edit:

```bash
$ vim $(grep -l 'Sampson' *)
...
```

The single quotation marks are not necessary in this example, but they are required if the regular expression you are searching for contains special characters or SPACES. It is generally a good habit to quote the pattern so that the shell does not interpret special characters it may contain.

**gzip: Compresses or decompresses files**

```bash
gzip [options] [file-list]
gunzip [options] [file-list]
zcat [file-list]
```

The gzip utility compresses files; gunzip restores files compressed with gzip; zcat displays files compressed with gzip.

**Arguments**

The file-list is a list of the names of one or more files that are to be compressed or decompressed. If a directory
The file-list is a list of the names of one or more files that are to be compressed or decompressed. If a directory appears in file-list with no recursive option, gzip/gunzip issues an error message and ignores the directory. With the recursive option, gzip/gunzip recursively compresses/decompresses files within the directory hierarchy.

If file-list is empty or if the special option is present, gzip reads from standard input. The stdout option causes gzip and gunzip to write to standard output.

The information in this section also applies to gunzip, a link to gzip.

Options

Accepts the common options described on page 587.

stdout  c  Writes the results of compression or decompression to standard output instead of overwriting the original file.

decompress or uncompress  d  Decompresses a file compressed with gzip. This option with gzip is equivalent to the gunzip command.

fast or best  n  Controls the tradeoff between the speed of compression and the amount of compression. The n is a digit from 1 to 9; level 1 is the fastest (least) compression and level 9 is the best (slowest and most) compression. The default level is 6. The options fast and best are synonyms for 1 and 9, respectively.

force  f  Overwrites an existing output file on compression/decompression.

list  l  For each compressed file in file-list, displays the file's compressed and decompressed sizes, the compression ratio, and the name of the file before compression. Use with verbose for additional information.

quiet  q  Suppresses warning messages.

recursive  r  Recursively descends directories in file-list and compresses/decompresses files within these directories.

test  t  Verifies the integrity of a compressed file. Displays nothing if the file is OK.

verbose  v  Displays the name of the file, the name of the compressed file, and the amount of compression as each file is processed.

Discussion

Compressing files reduces disk space requirements and the time needed to transmit files between systems. When gzip compresses a file, it adds the extension.gz to the filename. For example, compressing the file fname creates the file fname.gz and deletes the original file. To restore fname, use the command gunzip with the argument fname.gz.

Almost all files become much smaller when compressed with gzip. On rare occasions a file will become larger, but only by a slight amount. The type of a file and its contents (as well as the n option) determine how much smaller a file becomes; text files are often reduced by 60 to 70 percent.

The attributes of a file, such as its owner, permissions, and modification and access times, are left intact when gzip compresses and gunzip decompresses a file.

If the compressed version of a file already exists, gzip reports that fact and asks for your confirmation before overwriting the existing file. If a file has multiple links to it, gzip issues an error message and exits. The force option

appears in file-list with no recursive option, gzip/gunzip issues an error message and ignores the directory. With the recursive option, gzip/gunzip recursively compresses/decompresses files within the directory hierarchy.
option overrides the default behavior in both of these situations.

Notes

For more information refer to "gzip: Compresses a File" on page 58.

In addition to the gzip format, gunzip recognizes several other compression formats, enabling gunzip to decompress files compressed with compress.

To see an example of a file that becomes larger when compressed with gzip, compare the size of a file that has been compressed once with the same file compressed with gzip again. Because gzip complains when you give it an argument with the extension .gz, you need to rename the file before compressing it a second time.

The tar utility with the z modifier (page 789) calls gzip.

The following related utilities display and manipulate compressed files. None of these utilities changes the files that it works on.

zcat file-list     Works like cat except that it uses gunzip to decompress file-list as it copies files to standard output.

zdiff [ options ] file1 [ file2 ]
     Works like diff (page 638) except that file1 and file2 are decompressed with gunzip as needed. The zdiff utility accepts the same options as diff. If you omit file2, zdiff compares file1 with the compressed version of file1.

zless file-list     Works like less except that it uses gunzip to decompress file-list as it displays files.

Examples

In the first example, gzip compresses two files. Then gunzip decompresses one of the files. When a file is compressed and decompressed, its size changes but its modification time remains the same:

$ ls -l

    total 175
  -rw-rw-r-- 1 alex group  33557 Jul 20 17:32 patch-2.0.7
  -rw-rw-r-- 1 alex group 143258 Jul 20 17:32 patch-2.0.8

$ gzip *

$ ls -l

    total 51
  -rw-rw-r-- 1 alex group   9693 Jul 20 17:32 patch-2.0.7.gz
  -rw-rw-r-- 1 alex group  40426 Jul 20 17:32 patch-2.0.8.gz
$ gunzip patch-2.0.7.gz
$ ls -l

total 75
-rw-rw-r-- 1 alex group 33557 Jul 20 17:32 patch-2.0.7
-rw-rw-r-- 1 alex group 40426 Jul 20 17:32 patch-2.0.8.gz

In the next example, the files in Jenny’s home directory are archived by using the cpio utility (page 619). The archive is compressed with gzip before it is written to tape:

$ find /home/jenny -depth -print | cpio -oBm | gzip >/dev/ftape

head: Displays the beginning of a file

head [options] [file-list]

The head utility displays the beginning (head) of a file. The utility takes its input from one or more files you specify on the command line or from standard input.

Arguments

The file-list is a list of the pathnames of the files that head displays. When you specify more than one file, head displays the filename before displaying the first few lines of each file. When you do not specify a file, head takes its input from standard input.

Options

Accepts the common options described on page 587.

 bytes= n [ u ]  c n [ u ]
Displays the first n bytes (characters) of a file. The u is an optional unit of measure that can be b (512-byte blocks), k (kilobyte or 1,024-byte blocks), or m (megabyte or 1,048,576-byte blocks). If you include the unit of measure, head counts by this unit instead of by bytes.

 lines= n  n
Displays the first n lines of a file. You can use in to specify n lines without using the lines keyword or the in option. If you specify a negative value for n, head displays all but the last n lines of the file.

 quiet  q
Suppresses header information when you specify more than one filename on the command line.

Notes
The **head** utility displays the first ten lines of a file by default.

**Examples**

The examples in this section are based on the following file:

```bash
$ cat eleven
line one
line two
line three
line four
line five
line six
line seven
line eight
line nine
line ten
line eleven
```

Without any arguments **head** displays the first ten lines of a file:

```bash
$ head eleven
line one
line two
line three
line four
line five
line six
line seven
line eight
```
line nine
line ten

The next example displays the first three lines (lines 3) of the file:

$ head --lines 3 eleven
line one
line two
line three

The following example is equivalent to the preceding one:

$ head -3 eleven
line one
line two
line three

The next example displays the first six characters (bytes 6) in the file:

$ head --bytes 6 eleven
line o$

The final example displays all but the last seven lines of the file:

$ head --lines=-7 eleven
line one
line two
line three
line four

kill: Terminates a process by PID
**kill [option] PID-list**

The `kill` utility terminates one or more processes by sending them signals. By default `kill` sends a software termination signal (signal number 15). For `kill` to work, the process must belong to the user executing `kill`, with one exception: Superuser can terminate any process.

**Arguments**

The **PID-list** is a list of process identification (PID) numbers of processes that `kill` is to terminate.

**Options**

You can specify a signal number or name, preceded by a hyphen, as an option to cause `kill` to send the signal you specify to the **PID-list**.

`l (list)` Displays a list of signals. (Do not specify **PID-list**.)

**Notes**

See also `killall` on page 695.

See Table 11-5 on page 494 for a list of signals. The command `kill l` displays a complete list of signal numbers and names.

In addition to the `kill` utility, `kill` is a builtin in the Bourne Again and TC Shells. The builtins work similarly to the utility described here. Give the command `/bin/kill` to use the `kill` utility and the command `kill` to use the builtin. It does not usually matter which you use.

The shell displays the PID number of a background process when you initiate the process. You can also use the `ps` utility to determine PID numbers.

If the software termination signal does not terminate a process, try using a KILL signal (signal number 9). A process can choose to ignore any signal except KILL.

The `kill` utility/builtin accepts job identifiers in place of the **PID-list**. Job identifiers consist of a percent sign (%) followed by either a job number or a string that uniquely identifies the job.

To terminate all processes that the current login process initiated and have the operating system log you out, give the command `kill %9 0`.

**caution: root: do not run kill with arguments of %9 0 or KILL 0**

If you run the command `kill %9 0` while you are logged in as Superuser, you will bring the system down.

**Examples**

The first example shows a command line executing the file `compute` as a background process and the `kill` utility terminating it:
$ compute &
[2] 259
$ kill 259
$ RETURN

[2]+ Terminated compute

The next example shows the `ps` utility determining the PID number of the background process running a program named `xprog` and the `kill` utility terminating `xprog` with the TERM signal:

$ ps

<table>
<thead>
<tr>
<th>PID</th>
<th>TTY</th>
<th>STAT</th>
<th>TIME</th>
<th>COMMAND</th>
</tr>
</thead>
<tbody>
<tr>
<td>116</td>
<td>1</td>
<td>S</td>
<td>0:00</td>
<td>-tcsh</td>
</tr>
<tr>
<td>128</td>
<td>1</td>
<td>S N</td>
<td>0:00</td>
<td>xinit /home/alex/.xinitrc --</td>
</tr>
<tr>
<td>137</td>
<td>1</td>
<td>S N</td>
<td>0:01</td>
<td>fvwm</td>
</tr>
<tr>
<td>138</td>
<td>p0</td>
<td>S N</td>
<td>0:00</td>
<td>-tcsh</td>
</tr>
<tr>
<td>161</td>
<td>p0</td>
<td>S N</td>
<td>0:10</td>
<td>xprog</td>
</tr>
<tr>
<td>262</td>
<td>p0</td>
<td>R N</td>
<td>0:00</td>
<td>ps</td>
</tr>
</tbody>
</table>

$ kill -TERM 161

killall: Terminates a process by name

`killall [option] name-list`

The `killall` utility sends signals to processes executing specified commands. For `killall` to work, the processes must belong to the user executing `killall`, with one exception: Superuser can terminate any process.

Arguments

The `name-list` is a SPACE-separated list of names of programs that are to receive signals.

Options
You can specify a signal number or name, preceded by a hyphen, as an option before the `name-list` to cause `killall` to send the signal you specify. By default `killall` sends software termination signals (signal number 15, SIGTERM).

- **interactive** `\[\text{\textbackslash i}\]` Prompts for confirmation before killing a process.
- **list** `\[\text{\textbackslash l}\]` Displays a list of signals (but `kill \[\text{\textbackslash l}\]` displays a better list). With this option `killall` does not accept a `name-list`.
- **quiet** `\[\text{\textbackslash q}\]` Does not display a message if `killall` fails to terminate a process.

**Notes**

See also `kill` on page 693.

See Table 11-5 on page 494 for a list of signals. The command `kill \[\text{\textbackslash l}\]` displays a complete list of signal numbers and names.

If the software termination signal does not terminate the process, try using a KILL signal (signal number 9). A process can choose to ignore any signal except KILL.

You can use `ps` (page 746) to determine the name of the program you want to terminate.

**Examples**

You can give the following commands to experiment with `killall`:

```bash
$ sleep 60 &
[1] 23274
$ sleep 50 &
[2] 23275
$ sleep 40 &
[3] 23276
$ sleep 120 &
[4] 23277
$ killall sleep
$ RETURN
[1] Terminated sleep 60
[2] Terminated sleep 50
```
If you want to terminate all instances of the Firefox browser, give the following command to determine how Firefox was called:

```
$ ps -ef | grep -i firefox
```

```
max 17517 17512  0 Apr02 ?        00:00:54 /usr/local/firefox/firefox-bin
max 19340  2787  0 00:33 pts/6    00:00:00 grep firefox
```

The next command, run as `root`, terminates all instances of the Firefox browser:

```
# killall firefox-bin
```

**less: Displays text files, one screen at a time**

`less [options] [file-list]`

The `less` utility displays text files, one screen at a time.

**Arguments**

The `file-list` is the list of files you want to view. If there is no `file-list`, `less` reads from standard input.

**Options**

Accepts the common options described on page 587.

- `-c` `clear-screen` Repaints the screen from the top line down instead of scrolling.
- `-e` `quit-at_eof` (exit) Normally `less` requires you to enter `q` to terminate. This option exits automatically the second time `less` reads the end of file.
- `-E` `QUIT-AT-EOF` (exit) Similar to `-e`, except that `less` exits automatically the first time it reads the end of file.
- `-f` `quit-if-one-screen` Displays the file and quits if the file can be displayed on a single screen.
- `-i` `ignore-case` Causes a search for a string of lowercase letters to match both uppercase and lowercase letters. This option is ignored if you give a pattern that includes uppercase letters.
- `-I` `IGNORE-CASE` Causes a search for a string of letters of any case to match both uppercase and lowercase letters, regardless of the case of the search pattern.
- `-m` `long-prompt` Reports the percentage of the file that you have viewed with each prompt. This
option causes `less` to display a prompt that is similar to the prompt used by `more`. It does not work when `less` reads from standard input because `less` has no way of determining how much input there is.

**LINE-NUMBERS**

- **N** Displays a line number at the start of each line.

- **Ps**

  Changes the short prompt string (the prompt that appears at the bottom of each screen of output) to `prompt`. Enclose `prompt` in quotation marks if it contains SPACEs. You can use special symbols in `prompt` that `less` will replace with other values when it displays the prompt. For example, `less` displays the current filename in place of `%f` in `prompt`. See the `less` man page for a list of these special symbols and descriptions of other prompts. Custom prompts are useful if you are running `less` from within another program and want to give instructions or information to the person who is using the program. The default prompt is the name of the file displayed in reverse video.

**squeeze-blank-lines**

- **s** Displays multiple, adjacent blank lines as a single blank line. When you use `less` to display text that has been formatted for printing with blank space at the top and bottom of each page, this option shortens these headers and footers to a single line.

- **tabs= n**

  Sets tab stops `n` characters apart. The default is eight characters.

- **window= n**

  Sets the scrolling size to `n` lines. The default is the size of the display. Each time you move forward or backward a page, you move `n` lines.

  **+ command**

  Any command you can give `less` while it is running can also be given as an option by preceding it with a plus sign (+) on the command line. See the "Commands" section. A command preceded by a plus sign on the command line is executed as soon as `less` starts and applies only to the first file.

  **++ command**

  Similar to +command except that command is applied to every file in file-list, not just the first.

Notes

The phrase "less is more" explains the origin of this utility. The `more` utility is the original Berkeley UNIX pager (also available under Linux). The `less` utility is similar to `more` but includes many enhancements. After displaying a screen of text, `less` displays a prompt and waits for you to enter a command. You can skip forward and backward in the file, invoke an editor, search for a pattern, or perform a number of other tasks.

See the v command in the next section for information on how you can edit the file you are viewing with less.

You can set the options to `less` either from the command line when you call `less` or by setting the `LESS` environment variable. For example, you can use the following command from `bash` to use `less` with the `-x4` and `-s` options.

```
$ export LESS="-x4 -s"
```
Normally you would set `LESS` in `~/.bash_profile` if you are using `bash` or in `~/.login` if you are using `tcsh`. Once you have set the `LESS` variable, `less` is invoked with the specified options each time you call it. Any options you give on the command line override the settings in the `LESS` variable. The `LESS` variable is used both when you call `less` from the command line and when `less` is invoked by another program, such as `man`. To specify `less` as the pager to use with `man` and other programs, set the environment variable `PAGER` to `less`. For example, with `bash` you can add the following line to `~/.bash_profile`:

```
export PAGER=less
```

Commands

Whenever `less` pauses, you can enter any of a large number of commands. This section describes some commonly used commands. Refer to the `less` `man` page for the full list of commands. The optional numeric argument `n` defaults to 1, with the exceptions noted. You do not need to follow these commands with a RETURN.

- `n b` or `n CONTROL-B` (backward) Scrolls backward `n` lines. The default value of `n` is the size of the screen.

- `n d` or `n CONTROL-D` (down) Scrolls forward `n` lines. The default value of `n` is one-half the screen size. When you specify `n`, it becomes the new default value for this command.

- `F` (forward) Scrolls forward. If the end of the input is reached, this command waits for more input and then continues scrolling. This command allows you to use `less` in a manner similar to `tail` if (page 783), except that `less` paginates the output as it appears.

- `n g` (go) Goes to line number `n`. This command may not work if the file is read from standard input and you have moved too far into the file. The default value of `n` is 1.

- `h` or `H` (help) Displays a summary of all available commands. The summary is displayed using `less`, as the list of commands is quite long.

- `n RETURN` or `n j` (jump) Scrolls forward `n` lines. The default value of `n` is 1.

- `q` or `:q` Terminates `less`.

- `n u` or `n CONTROL-U` Scrolls backward `n` lines. The default value of `n` is one-half the screen size. When you specify `n`, it becomes the default value for this command.

- `v` Brings the current file into an editor with the cursor on the current line. The `less` utility uses the editor specified in the `EDITOR` environment variable. If `EDITOR` is not set, `less` uses `vi` (which is typically linked to `vim`).

- `n w` Scrolls backward like `n b`, except that the value of `n` becomes the new default value for this command.

- `n y` or `n k` Scrolls backward `n` lines. The default value of `n` is 1.

- `n z` Displays the next `n` lines like `n SPACE` except that the value of `n`, if present, becomes the new default value for the `z` and `SPACE` commands.

- `n SPACE` Displays the next `n` lines. Pressing `SPACE` by itself displays the next screen of text.

```
/ regular-expression
```

Skips forward in the file, looking for lines that contain a match for `regular-expression`. If you begin `regular-expression` with an exclamation point (!), this command looks for lines that do **not** contain a match for `regular-expression`. If `regular-expression` begins with an asterisk (*), this command continues the search through `file-list` (A normal search stops at the end of the current file.) If `regular-expression` begins with an at sign (@), this command begins the search at the start of `file-list` and continues to the end of `file-list`.

```
? regular-expression
```
This command is similar to the previous one but searches backward through the file (and file-list). An asterisk (*) as the first character in regular-expression causes the search to continue backward through file-list to the beginning of the first file. An at sign (@) causes the search to start with the last line of the last file in file-list and progress toward the first line of the first file.

{ or ( or [     If one of these characters appears in the top line of the display, this command scrolls forward to the matching right brace, parenthesis, or bracket. For example, typing { causes less to move the cursor forward to the matching }.
} or ) or ]     Similar to the preceding commands, these commands move the cursor backward to the matching left brace, parenthesis, or bracket.
CONTROL-L Redraws the screen. This command is useful if the text on the screen has become garbled.
[ n ] :n     Skips to the next file in file-list. If n is given, skips to the nth next file in file-list.
! [ command line ] Executes command line under the shell specified by the SHELL environment variable, or sh (usually linked to bash) by default. A percent sign (%) in command line is replaced by the name of the current file. If you omit command line, less starts an interactive shell.

Examples

The following example displays the file memo.txt. To see more of the file, the user presses the SPACE bar in response to the less prompt at the bottom left of the screen:

```
$ less memo.txt
...
memo.txt SPACE
...
```

In the next example, the user changes the prompt to a more meaningful message and uses the `N` option to display line numbers. Finally the user instructs less to skip forward to the first line containing the string procedure.

```
$ less -Ps"Press SPACE to continue, q to quit" -N +/procedure ncut.icn
  28  procedure main(args)
  29     local filelist, arg, fields, delim
  30
  31     filelist:=[]
...
  45     # Check for real field list
  46     #
  47     if /fields then stop("-fFIELD_LIST is required.")
```
# Process the files and output the fields

Press SPACE to continue, q to quit

**ln**: Makes a link to a file

```
ln [options] existing-file [new-link]
ln [options] existing-file-list directory
```

The `ln` utility creates hard or symbolic links to one or more files. You can create a symbolic link, but not a hard link, to a directory.

**Arguments**

In the first format the `existing-file` is the pathname of the file you want to create a link to. The `new-link` is the pathname of the new link. When you are creating a symbolic link, the `existing-file` can be a directory. If you omit `new-link`, `ln` creates a link to `existing-file` in the working directory, and uses the same simple filename as `existing-file`.

In the second format the `existing-file-list` is a list of the pathnames of the ordinary files you want to create links to. The `ln` utility establishes the new links in the `directory`. The simple filenames of the entries in the `directory` are the same as the simple filenames of the files in the `existing-file-list`.

**Options**

- **backup** (-b) If the `ln` utility will remove a file, this option makes a backup by appending `~` to the filename. This option works only with `force`.
- **force** (-f) Normally `ln` does not create the link if `new-link` already exists. This option removes `new-link` before creating the link. When you use `force` and `backup` together, `ln` makes a copy of `new-link` before removing it.
- **interactive** (-i) If `new-link` already exists, this option prompts you before removing `new-link`. If you enter `y` or `yes`, `ln` removes `new-link` before creating the link. If you answer `n` or `no`, no new link is made.
- **symbolic** (-s) Creates a symbolic link. When you use this option, the `existing-file` and `new-link` may be directories and may reside on different filesystems. Refer to "Symbolic Links" on page 99.

**Notes**

For more information refer to "Links" on page 96. The `ls` utility with the `-i` option displays the number of hard links to a file (Figure 4-12, page 92).

**Hard links**

By default `ln` creates **hard links**. A hard link to a file is indistinguishable from the original file. All hard links to a
file must be in the same filesystem. For more information refer to "Hard Links" on page 97.

Symbolic links

You can also use `ln` to create symbolic links. Unlike a hard link, a symbolic link can exist in a different filesystem from the linked-to file. Also, a symbolic link can point to a directory. For more information refer to "Symbolic Links" on page 99.

If `new-link` is the name of an existing file, `ln` does not create the link unless you use the `force` option or answer `yes` when using the `interactive` option.

Examples

The following command creates a link between `memo2` in the `/home/zach/literature` directory and the working directory. The file appears as `memo2` (the simple filename of the existing file) in the working directory:

```
$ ln /home/zach/literature/memo2 .
```

You can omit the period that represents the working directory from the preceding command. When you give a single argument to `ln`, it creates a link in the working directory.

The next command creates a link to the same file. This time the file appears as `new_memo` in the working directory:

```
$ ln /home/zach/literature/memo2 new_memo
```

The following command creates a link that causes the file to appear in another user's directory:

```
$ ln /home/zach/literature/memo2 /home/jenny/new_memo
```

You must have write and execute access permission to the other user's directory for this command to work. If you own the file, you can use `chmod` to give the other user write access permission to the file.

The next command creates a symbolic link to a directory. The `ls -ld` command shows the link:

```
$ ln -s /usr/local/bin bin
$ ls -ld bin
lrwxrwxrwx 1 zach zach 14 Feb 10 13:26 bin -> /usr/local/bin
```

The final example attempts to create a symbolic link named `memo1` to the file `memo2`. Because the file `memo1` exists, `ln` refuses to make the link. When you use the `interactive` option, `ln` asks whether you want to replace the existing `memo1` file with the symbolic link. If you enter `y` or `yes`, `ln` creates the link and the old `memo1` disappears.

```
$ ls -l memo?
```
You can also use the `force` option to cause `ln` to overwrite a file.

**lpr:** Sends files to printers

```
lpr [options] [file-list]
lpq [options] [job-identifiers]
lprm [options] [job-identifiers]
```

The `lpr` utility places one or more files into a print queue, providing orderly access to printers for several users or processes. The utility can work with printers attached to remote systems. You can use the `lprm` utility to remove files from the print queues and the `lpq` utility to check the status of files in the queues. Refer to "Notes" later in this section.

**Arguments**

The **file-list** is a list of one or more filenames for `lpr` to print. Often these files are text files, but many systems are configured so that `lpr` can accept and properly print a variety of file types. Without a **file-list**, `lpr` accepts input from standard input.

The **job-identifiers** is a list of job numbers or user names. If you do not know the job number of a print job, use `lpq` to display a list of print jobs.

**Options**

Some of the following options depend on the type of file being printed as well as on how the system is configured for printing.

- **l** (lowercase "l") Specifies that `lpr` should not preprocess (filter) the file being printed. Use this option when the file is already formatted for the printer.
Routes the print jobs to the queue for the printer named `printer`. If you do not use this option, print jobs are routed to the default printer for the local system. The acceptable values for `printer` are found in the file `/etc/printcap` and vary from system to system.

`r (remove)` Deletes the files in `file-list` after calling `lpr`.

`# n` Prints `n` copies of each file. Depending on which shell you are using, you may need to escape the `#` with a backslash to pass it to `lpr`.

**Discussion**

The `lpr` utility takes input from files you specify on the command line or from standard input and adds the files to the print queue as print jobs. The utility assigns a unique identification number to each print job. The `lpq` utility displays the job numbers of the print jobs that `lpr` has set up; you can use the `lprm` utility to remove a print job from the print queue.

### `lpq`

The `lpq` utility displays information about jobs in a print queue. When called without any arguments, `lpq` lists all the print jobs queued for the default printer. Use `lpr`'s `-P printer` option with `lpq` to look at other print queues—even those for printers connected to other systems. With the `-l` option `lpq` displays more information about each job. If you give the username of a user as an argument, `lpq` displays only the printer jobs belonging to that user.

### `lprm`

One item displayed by `lpq` is the job number for each print job in the queue. To remove a job from the print queue, use the job number as an argument to `lprm`. Unless you are Superuser, you can remove only your own jobs. Even as Superuser you may not be able to remove a job from a queue for a remote printer. If you do not give any arguments to `lprm`, it removes the currently active printer job (that is, the job that is now printing) from the queue, if you own that job.

**Notes**

If you normally use a printer other than the system default printer, you can set up `lpr` to use another printer as your personal default by assigning the name of this printer to the environment variable `PRINTER`. For example, if you use `bash`, you can add the following line to `~/.bash_profile` to set your default printer to the printer named `ps`:

```
export PRINTER=ps
```

**LPD and LPR**

Traditionally, UNIX had two printing systems: the BSD Line Printer Daemon (LPD) and the System V Line Printer system (LPR). Linux adopted those systems at first, and both UNIX and Linux have seen modifications to and replacements for these systems. Today CUPS is the default printing system under many Linux distributions.
CUPS (Common UNIX Printing System) is a cross-platform print server built around IPP (Internet Printing Protocol), which is based on HTTP. CUPS provides a number of printer drivers and can print different types of files, including PostScript files. CUPS provides System V and BSD command line interfaces and, in addition to IPP, supports LPD/LPR, HTTP, SMB, and JetDirect (socket) protocols, among others.

This section describes the LPD command line interface that runs under CUPS and also in native mode on older systems.

Examples

The first command sends the file named `memo2` to the default printer:

```
$ lpr memo2
```

Next a pipe sends the output of `ls` to the printer named `deskjet`:

```
$ ls | lpr -Pdeskjet
```

The next example paginates and sends the file `memo` to the printer:

```
$ pr -h "Today's memo" memo | lpr
```

The next example shows a number of print jobs queued for the default printer. Alex owns all of these jobs, and the first one is currently being printed (active). Jobs 635 and 639 were created by sending input to `lpr`'s standard input; job 638 was created by giving `ncut.icn` as an argument to the `lpr` command. The last column gives the size of each print job.

```
$ lpq

deskjet is ready and printing

<table>
<thead>
<tr>
<th>Rank</th>
<th>Owner</th>
<th>Job</th>
<th>Files</th>
<th>Total Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>alex</td>
<td>635</td>
<td>(stdin)</td>
<td>38128 bytes</td>
</tr>
<tr>
<td>1st</td>
<td>alex</td>
<td>638</td>
<td>ncut.icn</td>
<td>3587 bytes</td>
</tr>
<tr>
<td>2nd</td>
<td>alex</td>
<td>639</td>
<td>(stdin)</td>
<td>3960 bytes</td>
</tr>
</tbody>
</table>
```

The next command removes job 638 from the default print queue:

```
$ lprm 638
```
**ls: Displays information about one or more files**

**ls [options] [file-list]**

The `ls` utility displays information about one or more files. It lists the information alphabetically by filename unless you use an option to change the order.

**Arguments**

When you do not provide an argument, `ls` displays the names of the visible files in the working directory (those files whose filenames do not begin with a period).

The **file-list** is a list of one or more pathnames of any ordinary, directory, or device files. It can include ambiguous file references.

When you specify a directory, `ls` displays the contents of the directory. It displays the name of the directory only when needed to avoid ambiguity, such as when the listing includes more than one directory. When you specify an ordinary file, `ls` displays information about that one file.

**Options**

The options determine the type of information `ls` displays, the manner in which it displays the information, and the order in which it is displayed. When you do not use an option, `ls` displays a short list that contains only the names of files.

- **all**  
  Includes invisible files (those with filenames that begin with a period) in the listing. Without this option `ls` does not list information about invisible files unless you list the name of an invisible file in the **file-list**. When you use this option with a **file-list** that includes an appropriate ambiguous file reference, `ls` displays information about invisible files. The * ambiguous file reference does not match a leading period in a filename (see page 129).

- **almost-all**  
  A  
  The same as **all** but does not list the . and .. entries.

- **escape**  
  Displays nonprinting characters in a filename, using backslash escape sequences similar to those used in C language strings. A partial list is given in **Table V-16**. Other nonprinting characters are displayed as a backslash followed by an octal number.

**Table V-16. Backslash escape sequences**

</tr>
<tr>
<td>\</td>
<td>BACKSLASH</td>
</tr>
</tbody>
</table>

- **color**  
  When  
  The `ls` utility can display various types of files in different colors but normally does not use colors (the same result as when you specify **when** as **none**). If you do not specify **when** or if you
specify \textit{when} as \texttt{always}, \texttt{ls} uses colors. When you specify \textit{when} as \texttt{auto}, \texttt{ls} uses colors only when the output goes to a screen. See \enquote{Notes} for more information.

\textbf{directory} \texttt{d} Displays the names of directories without displaying their contents. Without an argument this option displays information about the working directory. It does not dereference symbolic links (it lists a link, not the directory it points to).

\textbf{format=} \texttt{word} By default \texttt{ls} displays files sorted vertically. This option sorts files based on \texttt{word}: \texttt{across} (\texttt{Wx}), separated by \texttt{commas} (\texttt{Im}), \texttt{horizontal} (\texttt{Xx}), \texttt{long} (\texttt{Il}), or \texttt{single-column} (\texttt{I1}).

\textbf{classify} \texttt{F} Displays a slash (/) after each directory, an asterisk (*) after each executable file, and an at sign (@) after a symbolic link.

\textbf{human-readable} \texttt{h} Displays sizes in K (kilobyte), M (megabyte), and G (gigabyte) blocks, as appropriate. Works with the \texttt{l} option only. This option uses powers of 1,024; use \texttt{si} for powers of 1,000.

\textbf{inode} \texttt{i} Displays the inode number of each file. With the \texttt{l} option this option displays the inode number in column 1 and shifts all other items one column to the right.

\textbf{format=} \texttt{long} \texttt{l} (lowercase \enquote{l\texttt{l}}) Lists more information about each file. Use this option with \texttt{lh} to make file sizes more readable. See \enquote{Discussion} for more information.

\textbf{dereference} \texttt{L} Lists information about the file referenced by a symbolic link rather than information about the link itself.

\textbf{hide-control-chars} \texttt{q} Displays nonprinting characters in a filename as question marks. When output is going to the screen, this is the default behavior.

\textbf{reverse} \texttt{r} Displays the list of filenames in reverse sorted order.

\textbf{recursive} \texttt{R} Recursively lists subdirectories.

\textbf{size} \texttt{s} Displays the number of 1,024-byte blocks allocated to the file. The size precedes the filename. With the \texttt{l} option this option displays the size in column 1 and shifts all other items one column to the right. You can include the \texttt{lh} option to make the file sizes easier to read.

\textbf{sort=} \texttt{word} By default \texttt{ls} displays files in ASCII order. This option sorts the files based on \texttt{word}: filename \texttt{extension} (\texttt{IX}), \texttt{none} (\texttt{IU}), file \texttt{size} (\texttt{IS}), \texttt{access} time (\texttt{IU}), or modification \texttt{time} (\texttt{It}). See \enquote{time} for an exception.

\textbf{time=} \texttt{word} By default \texttt{ls} with the \texttt{l} option displays the modification time of a file. Set \texttt{word} to \texttt{atime} to display the access time (or use the \texttt{lt} option) or to \texttt{ctime} to display the creation time. The list is sorted by \texttt{word} when you also give the \texttt{sort=word} option.

\texttt{x} Displays files sorted by lines (the default display is sorted by columns).

\texttt{X} Displays files sorted by filename extension. Files with no filename extension are listed first.

\texttt{1} (one) Displays files one per line.

\textbf{Discussion}

The \texttt{ls} long listing (\textbf{format}=	exttt{long} or \texttt{l} options) displays the seven columns shown in Figure 4-12 on page 92. The first column, which contains 11 characters, is divided as described in the following paragraphs. The first character describes the type of file, as shown in Table V-17.

\begin{table}[h]
\centering
\caption{First character in a long \texttt{ls} display}
\begin{tabular}{|c|c|}
\hline
Character & Meaning \\
\hline
- & Ordinary \\
\hline
\end{tabular}
\end{table}
<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>Block device</td>
</tr>
<tr>
<td>c</td>
<td>Character device</td>
</tr>
<tr>
<td>d</td>
<td>Directory</td>
</tr>
<tr>
<td>p</td>
<td>FIFO (named pipe)</td>
</tr>
<tr>
<td>l</td>
<td>Symbolic link</td>
</tr>
</tbody>
</table>

The next nine characters of the first column represent the access permissions associated with the file. They are divided into three sets of three characters each.

The first three characters represent the owner's access permissions. If the owner has read access permission to the file, r appears in the first character position. If the owner is not permitted to read the file, a hyphen appears in this position. The next two positions represent the owner's write and execute access permissions. If w appears in the second position the owner is permitted to write to the file; if x appears in the third position the owner is permitted to execute the file. An s in the third position indicates that the file has setuid permission and execute permission. An S indicates setuid without execute permission. A hyphen indicates that the owner does not have the access permission associated with the character position.

In a similar manner the second and third sets of three characters represent the access permissions of the group the file is associated with and of other users. An s in the third position of the second set of characters indicates that the file has setgid permission with execute permission, and an S indicates setgid without execute permission.

The last character is t if the sticky bit (page 903) is set with execute permission and T if it is set without execute permission. Refer to chmod on page 604 for information on changing access permissions.

Figure 4-12 on page 92 illustrates the columns described in the following paragraphs.

The second column indicates the number of hard links to the file. Refer to page 96 for more information on links.

The third and fourth columns display the name of the owner of the file and the name of the group the file is associated with.

The fifth column indicates the size of the file in bytes or, if information about a device file is being displayed, the major and minor device numbers. In the case of a directory, this number is the size of the directory file, not the size of the files that are entries within the directory. (Use du to display the sum of the sizes of all files in a directory.) Use the -h option to display the size of files in kilobytes, megabytes, or gigabytes.

The last two columns display the date and time the file was last modified and the filename, respectively.

Notes

Refer to page 127 for examples of using ls with ambiguous file references.

With the -color option ls displays filenames of various types of files in different colors. By default executable files are green, directory files are blue, symbolic links are cyan, archives and compressed files are red, and ordinary text files are black. The manner in which ls colors the various file types is specified in the /etc/DIR_COLORS file. If this file does not exist on the local system, ls will not color filenames. You can modify /etc/DIR_COLORS to alter the default color/filetype mappings on a systemwide basis. For your personal use, you can copy /etc/DIR_COLORS to the ~/.dir_colors file in your home directory and modify it. For your login, ~/.dir_colors overrides the systemwide colors established in /etc/DIR_COLORS. Refer to the dir_colors and dircolors man pages for more information.
Examples

The first command line shows the `ls` utility with the `-x` option, which sorts the files horizontally. The `ls` utility displays an alphabetical list of the names of the files in the working directory:

```
$ ls -x
bin     c     calendar
execute letters shell
```

The `-F` option appends a slash (`/`) to files that are directories, an asterisk to files that are executable, and an at sign (`@`) after symbolic links:

```
$ ls -Fx
bin/  c/  calendar
execute* letters/ shell@
```

Next the `-l` (long) option displays a long list. The files are still in alphabetical order:

```
$ ls -l
  total 8
  drwxrwxr-x  2 jenny pubs   80  May 20 09:17 bin
  drwxrwxr-x  2 jenny pubs  144  Mar 26 11:59 c
  -rw-rw-r--  1 jenny pubs  104  May 28 11:44 calendar
  -rw-rw-r--  1 jenny pubs   85  May  6 08:27 execute
  drwxrwxr-x  2 jenny pubs   32  Oct  6 22:56 letters
  drwxrwxr-x 16 jenny pubs  1296  Jun  6 17:33 shell
```

The `-a` (all) option lists all files, including invisible ones:

```
$ ls -a
.  .profile  c  execute  shell
..  bin  calendar  letters
```
Combining the \texttt{a} and \texttt{l} options displays a long listing of all files, including invisible files, in the working directory. This list is still in alphabetical order:

\begin{verbatim}
$ ls -al

   total 12
   drwxrwxr-x  6 jenny pubs  480 Jun  6 17:42 .
   drwxrwx--- 26 root root 816 Jun  6 14:45 ..
-rw-rw-r--  1 jenny pubs 161 Jun  6 17:15 .profile
drwxrwxr-x  2 jenny pubs  80 May 20 09:17 bin
drwxrwxr-x  2 jenny pubs 144 Mar 26 11:59 c
-rw-rw-r--  1 jenny pubs 104 May 28 11:44 calendar
-rwxrw-r--  1 jenny pubs  85 May  6 08:27 execute
drwxrwxr-x  2 jenny pubs  32 Oct  6 22:56 letters
drwxrwxr-x 16 jenny pubs 1296 Jun  6 17:33 shell
\end{verbatim}

When you add the \texttt{r} (reverse) option to the command line, \texttt{ls} produces a list in reverse alphabetical order:

\begin{verbatim}
$ ls -ral

   total 12
   drwxrwxr-x 16 jenny pubs 1296 Jun  6 17:33 shell
drwxrwxr-x  2 jenny pubs  32 Oct  6 22:56 letters
-rwxrw-r--  1 jenny pubs  85 May  6 08:27 execute
-rw-rw-r--  1 jenny pubs 104 May 28 11:44 calendar
drwxrwxr-x  2 jenny pubs 144 Mar 26 11:59 c
drwxrwxr-x  2 jenny pubs  80 May 20 09:17 bin
-rw-rw-r--  1 jenny pubs 161 Jun  6 17:15 .profile
drwxrwx--- 26 root root 816 Jun  6 14:45 ..
drwxrwxr-x  6 jenny pubs  480 Jun  6 17:42 .
\end{verbatim}

Use the \texttt{t} and \texttt{l} options to list files so that the most recently modified file appears at the top of the list:
Together the `-r` and `-t` options cause the file you modified least recently to appear at the top of the list.

The next example shows `ls` with a directory filename as an argument. The `ls` utility lists the contents of the directory in alphabetical order:

```
$ ls bin

  c    e      lsd
```

To display information about the directory file itself, use the `-d` (directory) option. This option lists information only about the directory:

```
$ ls -dl bin

  drwxrwxr-x 2 jenny pubs 80 May 20 09:17 bin
```
You can use the following command to display a list of all invisible filenames (those starting with a period) in your home directory. This is a convenient way to list the initialization files in your home directory:

```
$ ls -d ~/.*
/home/sam/.  /home/sam/.gtkrc-kde
/home/sam/..  /home/sam/.history
...
```
make: Keeps a set of programs current

```
make [options] [target-files] [arguments]
```

The GNU `make` utility keeps a set of executable programs current, based on differences in the modification times of the programs and the source files that each program is dependent on.

Arguments

The `target-files` refer to targets on dependency lines in the makefile. When you do not specify a `target-file`, `make` updates the target on the first dependency line in the makefile. Command line `arguments` of the form `name = value` set the variable `name` to `value` inside the makefile. See "Discussion" for more information.

Options

If you do not use the `-f` option, `make` takes its input from a file named `GNUmakefile`, `makefile`, or `Makefile` (in that order) in the working directory. In this section, this input file is referred to as `makefile`. Many users prefer to use the name `Makefile` because it shows up earlier in directory listings.

- `-C directory`
  Changes directories to `directory` before starting.

- `-d` (debug)
  Displays information about how `make` decides what to do.

- `-f file`
  (input file)
  Uses `file` as input instead of `makefile`.

- `-j n`
  (jobs)
  Runs up to `n` commands at the same time instead of the default of one command. Running multiple commands simultaneously is especially effective if you are running Linux on a multiprocessor system. If you omit `n`, `make` does not limit the number of simultaneous jobs.

- `-k`
  Continues with the next file from the list of `target-files` instead of quitting when a construction command fails.

- `-n` (no execution)
  Displays, but does not execute, the commands that `make` would execute to bring the `target-files` up-to-date.

- `-s` (silent)
  Does not display the names of the commands being executed.

- `-t` (touch)
  Updates the modification times of target files but does not execute any construction commands (page 403). Refer to `touch` on page 801.

Discussion

The `make` utility bases its actions on the modification times of the programs and the source files that each program is dependent on. Each of the executable programs, or `target-files`, is dependent on one or more prerequisite files. The relationships between `target-files` and prerequisites are specified on `dependency lines` in a makefile. Construction commands follow the dependency line, specifying how `make` can update the `target-files`.

Documentation

Refer to page 399 for more information about `make` and makefiles. For additional information refer to www.gnu.org/software/make/manual/make.html and to the `make info` page.
Although the most common use of make is to build programs from source code, this general-purpose build utility is suitable for a wide range of applications. Anywhere you can define a set of dependencies to get from one state to another represents an ideal candidate for using make.

Much of make's power derives from the features you can set up in a makefile. For example, you can define variables using the same syntax found in the Bourne Again Shell. Always define the variable SHELL in a makefile; set it to the pathname of the shell you want to use when running construction commands. To define the variable and assign it a value, place the following line near the top of a makefile:

```
SHELL=/bin/sh
```

Assigning the value /bin/sh to SHELL allows you to use a makefile on other computer systems. On Linux systems /bin/sh is generally linked to /bin/bash. The make utility uses the value of the environment variable SHELL if you do not set SHELL in a makefile. If SHELL does not hold the path of the shell you intended to use and if you do not set SHELL in a makefile, the construction commands may fail.

Following is a list of additional features associated with make:

- You can run specific construction commands silently by preceding them with an @ sign. For example, the following lines will display a short help message when you run the command make help:

```
help:
    @echo "You can make the following:"
    @echo "  "
    @echo "libbuf.a    -- the buffer library"
    @echo "Bufdisplay -- display any-format buffer"
    @echo "Buf2ppm    -- convert buffer to pixmap"
```

Without the @ signs in the preceding example, make would display each of the echo commands before executing it. This way of displaying a message works because no file is named help in the working directory. As a result make runs the construction commands in an attempt to build this file. Because the construction commands display messages but do not build the file help, you can run make help repeatedly with the same result.

- You can cause make to ignore the exit status of a command by preceding the command with a hyphen (-). For example, the following line allows make to continue regardless of whether the call to /bin/rm is successful (the call to /bin/rm fails if libbuf.a does not exist):

```
-/-bin/rm libbuf.a
```
You can use special variables to refer to information that might change from one use of `make` to the next. Such information might include the files that need updating, the files that are newer than the target, or the files that match a pattern. For example, you can use the variable `$?` in a construction command to identify all prerequisite files that are newer than the target file. This variable allows you to print any files that have changed since the last time you printed files out:

```
list:     .list
.list:    Makefile buf.h xtbuff_ad.h buff.c buf_print.c xtbuff.c
pr $? | lpr
date > .list
```

The target list depends on the source files that might be printed. The construction command `pr $? | lpr` prints only those source files that are newer than the file `.list`. The line `date > .list` modifies the `.list` file so that it is newer than any of the source files. The next time you run the command `make list`, only the files that have been changed are printed.

You can include other makefiles as if they were part of the current makefile. The following line causes `make` to read `Make.config` and treat the contents of that file as though it were part of the current makefile, allowing you to put information common to more than one makefile in a single place:

```
include Make.config
```

Notes

The section "make: Keeps a Set of Programs Current" on page 399 provides more information about `make`.

Examples

The first example causes `make` to bring the `target-file` named `analysis` up-to-date by issuing three `cc` commands. It uses a makefile named `GNUmakefile`, `makefile`, or `Makefile` in the working directory.

```
$ make analysis
cc - c analy.c
cc - c stats.c
cc - o analysis analy.o stats.o
```

The following example also updates `analysis` but uses a makefile named `analysis.mk` in the working directory:
$ make -f analysis.mk analysis

'analysis' is up to date.

The next example lists the commands \texttt{make} would execute to bring the \texttt{target-file} named \texttt{credit} up-to-date. Because of the \texttt{n (no-execution)} option, \texttt{make} does not execute the commands.

$ make -n credit

\texttt{cc - c - O credit.c}

\texttt{cc - c - O accounts.c}

\texttt{cc - c - O terms.c}

\texttt{cc - o credit credit.c accounts.c terms.c}

The next example uses the \texttt{t} option to update the modification time of the \texttt{target-file} named \texttt{credit}. After you use this option, \texttt{make} thinks that \texttt{credit} is up-to-date.

$ make -t credit

$ make credit

'credit' is up to date.

Next is a simple makefile for building a utility named \texttt{ff}. Because the \texttt{cc} command needed to build \texttt{ff} is complex, using a makefile allows you to rebuild \texttt{ff} easily, without having to remember and retype the \texttt{cc} command.

$ cat Makefile

\texttt{# Build the ff command from the fastfind.c source}

\texttt{SHELL=/bin/sh}

\texttt{ff:}

\texttt{cc -traditional -O2 -g -DBIG=5120 -o ff fastfind.c myClib.a}

$ make ff

\texttt{cc -traditional -O2 -g -DBIG=5120 -o ff fastfind.c myClib.a}
The following example shows a much more sophisticated makefile that uses features not discussed in this section. Refer to the sources cited under "Documentation" on page 716 for information about these and other advanced features.

$ cat Makefile

#########################################################################
## build and maintain the buffer library
#########################################################################

SHELL=/bin/sh

#########################################################################
## Flags and libraries for compiling. The XLDLIBS are needed
## whenever you build a program using the library. The CCFLAGS
## give maximum optimization.

CC=gcc

xtbuff.o: $(INCLUDES) $(XINCLUDES) xtbuff.c

$(CC) -c $(CCFLAGS) xtbuff.c

The make utility can be used for tasks other than compiling code. As a final example, assume that you have a database that lists IP addresses and the corresponding hostnames in two columns and that the database dumps these values to a file named hosts.tab. You need to extract only the hostnames from this file and generate a Web page named hosts.html containing these names. The following makefile is a simple report writer:

$ cat makefile
#
SHELL=/bin/bash
#
hosts.html: hosts.tab
    @echo "<HTML><BODY>" > hosts.html
    @awk '{print $$2, "<br>"}'} hosts.tab >> hosts.html
    @echo "</BODY></HTML>" >> hosts.html

man: Displays documentation for commands

man [options] [section] command
man k keyword

The man utility provides online documentation for Linux commands. In addition to user commands, documentation is available for many other commands and details that relate to Linux. Because many Linux commands come from GNU, the GNU info utility (page 32) frequently provides more complete information.

A one-line header is associated with each manual page. This header consists of a command name, the section of the manual in which the command is found, and a brief description of what the command does. These headers are stored in a database so that you can perform quick searches on keywords associated with each man page.

Arguments

The section argument tells man to limit its search to the specified section of the manual (see page 30 for a listing of manual sections). Without this argument man searches the sections in numerical order and displays the first man page it finds. In the second form of the man command, the k option searches for the keyword in the database of
**man** page headers; **man** displays a list of headers that contain the *keyword*. A **man** **k** command performs the same function as **apropos** (page 62).

**Options**

-a Displays **man** pages for all sections of the manual. Without this option **man** displays only the first page it finds. Use this option when you are not sure which section contains the information you are looking for.

-k **keyword**

Displays manual page headers that contain the string **keyword**. You can scan this list for commands of interest. This option is equivalent to the **apropos** command (page 62).

-K **keyword**

Searches for **keyword** in all **man** pages. This option can take a long time to run.

-M **path**

Searches the directories in **path** for **man** pages, where **path** is a colon-separated list of directories.

-t Formats the page for printing on a PostScript printer. The output goes to standard output output.

**Discussion**

The manual pages are organized in sections, each pertaining to a separate aspect of the Linux system. Section 1 contains user-callable commands and is the section most likely to be accessed by users who are not system administrators or programmers. Other sections of the manual describe system calls, library functions, and commands used by system administrators. See page 30 for a listing of the manual sections.

**Pager**

The **man** utility uses **less** to display manual pages that fill more than one screen. To change to another pager, set the environment variable **PAGER** to the pathname of the pager you want to use. For example, adding the following line to the ~/.bash_profile file allows a **bash** user to use **more** instead of **less**:

```
export PAGER=/bin/more
```

**MANPATH**

You can tell **man** where to look for **man** pages by setting the environment variable **MANPATH** to a colon-separated list of directories. For example, **bash** users can add the following line to ~/.bash_profile to cause **man** to search the /usr/man, /usr/local/man, and /usr/X11R6/man directories:

```
export MANPATH=/usr/man:/usr/local/man:/usr/X11R6/man
```

You can edit /etc/man.config to further configure **man**. Refer to the **man** page for more information.

**Notes**
The argument to **man** is not always a command name. For example, the command **man ascii** lists the ASCII characters and their various representations; the command **man \( \text{\texttt{k postscript}} \)** lists **man** pages that pertain to PostScript.

The **man** pages are commonly stored in unformatted, compressed form. When you request a **man** page, it has to be decompressed and formatted before being displayed. To speed up subsequent requests for that **man** page, **man** attempts to save the formatted version of the page.

Some utilities described in the manual pages have the same name as shell builtin commands. The behavior of the shell builtin may differ slightly from the behavior of the utility as described in the manual page.

**Examples**

The following example uses **man** to display the documentation for the command **write**, which sends messages to another user's terminal:

```
$ man write

WRITE(1)          Linux Programmer's Manual          WRITE(1)

NAME

   write - send a message to another user

SYNOPSIS

   write user [ttyname]

DESCRIPTION

   Write allows you to communicate with other users, by copy-
   ing lines from your terminal to theirs.

   When you run the write command, the user you are writing
   ...

```

The next example displays the **man** page for another command—the **man** command itself, a good starting place for someone learning about the system:

```
$ man man
```
NAME

man - format and display the online manual pages
manpath - determine users search path for man pages

SYNOPSIS

DESCRIPTION

man formats and displays the online manual pages. If you specify section, man only looks in that section of the ...

The next example shows how you can use the man utility to find the man pages that pertain to a certain topic. In this case man $k displays man page headers containing the string latex. The apropos utility (a shell script stored in /usr/bin/apropos) functions similarly to man $k.

$ man -k latex

Pod::LaTeX (3pm) - Convert Pod data to formatted Latex
einitex [elatex] (1) - extended TeX
elatex [latex] (1) - structured text formatting and typesetting
etex [elatex] (1) - extended TeX
evirtex [elatex] (1) - extended TeX
lambda [latex] (1) - structured text formatting and typesetting
The search for the keyword entered with the `k` option is not case sensitive. Although the keyword entered on the command line is all lowercase, it matches the first header, which contains the string `LaTeX` (uppercase and lowercase). The **3pm** on the first line indicates that the *man* page is from Section 3 (Subroutines) of the Linux System Manual and comes from the *Perl Programmers Reference Guide* (it is a Perl subroutine; see [www.perl.org](http://www.perl.org) for more information on the Perl programming language).

**mkdir: Creates a directory**

`mkdir [option] directory-list`

The `mkdir` utility creates one or more directories.

**Arguments**

The *directory-list* is a list of one or more pathnames of directories that `mkdir` creates.

**Options**

Accepts the *common options* described on page 587.

- `mode= mode` Sets the permission to *mode*. You can represent the *mode* absolutely by using an octal number (page 605) or symbolically (see Table V-4 on page 604).

- `parents` Creates any directories that do not exist in the path to the directory you wish to create.

- `verbose` Displays the name of each directory created. This option is helpful when used with the `parents` option.

**Notes**

You must have permission to write to and search (execute permission) the parent directory of the directory you are creating. The `mkdir` utility creates directories that contain the standard invisible entries (`.` and `..`).

**Examples**

The following command creates the *accounts* directory as a subdirectory of the working directory and the *prospective* directory as a subdirectory of *accounts*:

```
$ mkdir --parents accounts/prospective
```

Without changing working directories, the same user creates another subdirectory within the *accounts* directory:
Next the user changes the working directory to the `accounts` directory and creates one more subdirectory:

```
$ cd accounts
$ mkdir closed
```

The last example shows the user creating another subdirectory. This time the `--mode` option removes all access permissions for group and others:

```
$ mkdir --mode go= accounts/past_due
```

**mkfs: Creates a filesystem on a device**

```
mkfs [options] device
```

The `mkfs` utility creates a filesystem on a device such as a floppy diskette or a partition of a hard disk. It acts as a front end for programs that create filesystems, each specific to a filesystem type.

**caution: mkfs destroys all data on a device**

Be careful when using `mkfs`, as it destroys all data on a device.

**Arguments**

The `device` is the name of the device that you want to create the filesystem on. If the device name is in `/etc/fstab`, you can use the mount point of the device instead of the device name.

**Options**

When you run `mkfs`, you can specify both global options and options specific to the filesystem type that `mkfs` is creating (for example, `ext2`, `ext3`, `msdos`, `reiserfs`). Global options must precede type-specific options.

**Global Options**

- `t fstype` (type) The `fstype` is the type of filesystem you want to create—for example, `ext2`, `ext3`, `msdos`, or `reiserfs`. The default filesystem varies between Linux distributions.

- `V` (verbose) Displays more output, including file-specific information.

**Filesystem Type-Specific Options**

The following options apply to many common filesystem types, including `ext2` and `ext3`. The following command
The following options apply to many common filesystem types, including \texttt{ext2} and \texttt{ext3}. The following command lists the filesystem creation utilities available on the local system:

\begin{verbatim}
$ ls /sbin/mkfs.*
/sbin/mkfs.cramfs  /sbin/mkfs.ext3   /sbin/mkfs.vfat
/sbin/mkfs.ext2    /sbin/mkfs.msdos
\end{verbatim}

There is frequently a link to \texttt{/sbin/mkfs.ext2} at \texttt{/sbin/mke2fs}. Review the \texttt{man} page or give the pathname of the filesystem creation utility to determine which options the utility accepts.

\begin{verbatim}
$ /sbin/mkfs.ext3
\end{verbatim}

\textbf{Usage:} \texttt{mkfs.ext3 [-c|-t|-l filename] [-b block-size] [-f fragment-size]}
\begin{verbatim}
[-m reserved-blocks-percentage] [-o creator-os] [-g blocks-per-group]
[-L volume-label] [-M last-mounted-directory] [-O feature[,...]]
[-r fs-revision] [-R options] [-qvSV] device [blocks-count]
\end{verbatim}

\textbf{b size}
\begin{verbatim}
( block ) Specifies the size of blocks in bytes. On \texttt{ext2} and \texttt{ext3} filesystems valid block sizes are 1,024, 2,048, and 4,096 bytes.
\end{verbatim}

\textbf{c ( check )} Checks for bad blocks on the device before creating a filesystem. Specify this option twice to perform a slow, destructive, read-write test.

\textbf{Discussion}

Before you can write to and read from a hard disk or floppy diskette in the usual fashion, there must be a filesystem on it. Typically a hard disk is divided into \texttt{partitions} (page 892), each with a separate filesystem. A floppy diskette normally holds a single filesystem. Refer to \texttt{Chapter 4} for more information on filesystems.

\textbf{Notes}

You can use \texttt{tune2fs} (page 808) with the \texttt{-j} option to change an existing \texttt{ext2} filesystem into a \textit{journaling filesystem} (page 883) of type \texttt{ext3}. (See "Examples." ) You can also use \texttt{tune2fs} to change how often \texttt{fsck} (page 666) checks a filesystem.

\texttt{mkfs} is a front end

Much like \texttt{fsck}, \texttt{mkfs} is a front end that calls other utilities to handle various types of filesystems. For example, \texttt{mkfs} calls \texttt{mke2fs} (which is typically linked to \texttt{mkfs.ext2} and \texttt{mkfs.ext3}) to create the widely used \texttt{ext2}.
and ext3 filesystems. Refer to the mke2fs man page for more information. Other utilities that mkfs calls are typically named mks. type, where type is the filesystem type. By splitting mkfs in this manner, filesystem developers can provide programs to create their filesystems without affecting the development of other filesystems or changing how system administrators use mkfs.

Examples

In the following example, mkfs creates a filesystem on the device at /dev/hda8. In this case the default filesystem type is ext2.

```
# /sbin/mkfs /dev/hda8
mke2fs 1.35 (28-Feb-2004)
max_blocks 1309867008, rsv_groups = 39974, rsv_gdb = 312
Filesystem label=
OS type: Linux
Block size=4096 (log=2)
Fragment size=4096 (log=2)
640000 inodes, 1279167 blocks
63958 blocks (5.00%) reserved for the super user
First data block=0
Maximum filesystem blocks=1312817152
40 block groups
32768 blocks per group, 32768 fragments per group
16000 inodes per group
Superblock backups stored on blocks:
32768, 98304, 163840, 229376, 294912, 819200, 884736

Writing inode tables: 0/40...39/40...done
inode.i_blocks = 19976, i_size = 4243456

Writing superblocks and filesystem accounting information: done
```
This filesystem will be automatically checked every 23 mounts or 180 days, whichever comes first. Use tune2fs -c or -i to override.

Next the administrator uses `tune2fs` to convert the `ext2` filesystem to an `ext3` journaling filesystem:

```
# /sbin/tune2fs -j /dev/hda8
```

tune2fs 1.35 (28-Feb-2004)

Creating journal inode: done

This filesystem will be automatically checked every 23 mounts or 180 days, whichever comes first. Use tune2fs -c or -i to override.

Mtools: Uses DOS-style commands on files and directories

- `mcd [directory]` Changes the working directory on the DOS disk
- `mcopy [options] file-list target` Copies DOS files from one directory to another
- `mdel file-list` Deletes DOS files
- `mdir [w] directory` Lists contents of DOS directories
- `mformat [options] device` Adds DOS formatting information to a disk
- `mtype [options] file-list` Displays the contents of DOS files

These utilities mimic DOS commands and manipulate Linux files or DOS files. The `mcopy` utility provides an easy way to move files between a Linux filesystem and a DOS disk. The default drive for all commands is `/dev/fd0` or `A:`.

Utilities

Table V-18 lists some of the utilities in the Mtools collection.

<table>
<thead>
<tr>
<th>Utility</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mcd</code></td>
<td>Changes the working directory on the DOS disk</td>
</tr>
<tr>
<td><code>mcopy</code></td>
<td>Copies DOS files from one directory to another</td>
</tr>
<tr>
<td><code>mdel</code></td>
<td>Deletes DOS files</td>
</tr>
<tr>
<td><code>mdir</code></td>
<td>Lists contents of DOS directories</td>
</tr>
<tr>
<td><code>mformat</code></td>
<td>Adds DOS formatting information to a disk</td>
</tr>
<tr>
<td><code>mtype</code></td>
<td>Displays the contents of DOS files</td>
</tr>
</tbody>
</table>
**Arguments**

The *directory*, used with *mcd* and *mdir*, must be the name of a directory on a DOS disk. The *file-list*, used with *mcopy* and *mtype*, is a SPACE-separated list of filenames. The *target*, used with *mcopy*, is the name of a regular file or a directory. If you give *mcopy* a *file-list* with more than one filename, *target* must be the name of a directory. The *device*, used with *mformat*, is the DOS drive letter containing the disk to be formatted (for example, *A:*).

**Options**

*mcopy*

- **n** Automatically replaces existing files without asking. Normally *mcopy* asks for verification before overwriting a file.
- **p** (preserve) Preserves the attributes of files when they are copied.
- **s** (recursive) Copies directories and their contents recursively.
- **t** (text) Converts DOS text files for use on a Linux system, and vice versa. Lines in DOS text files are terminated with the character pair RETURN-NEWLINE; lines in Linux text files end in NEWLINE. This option removes the RETURN character while copying from a DOS file and adds it when copying from a Linux file.

*mdir*

- **w** (wide) Displays only filenames and fits as many as possible on each line. By default *mdir* lists information about each file on a separate line, showing filename, size, and creation time.

*mformat*

- **f 1440**
  - Specifies a 1,440K 3.5-inch HD floppy diskette.
- **f 2880**
  - Specifies a 2,880K 3.5-inch ED floppy diskette.
- **v** vol
  - (label) Puts *vol* as the volume label on the newly formatted DOS disk.

*mtype*

- **t** (text) Similar to the *t* option for *mcopy*, this option replaces each RETURN-NEWLINE character pair in the DOS file with a single NEWLINE character before displaying the file.

**Discussion**

Although these utilities mimic their DOS counterparts, they do not attempt to match those tools exactly. In most cases restrictions imposed by DOS are removed. For example, the asterisk ambiguous file reference (*) matches all filenames (as it does under Linux), including those filenames that DOS would require **.* to match.
Notes

In this discussion, the term **DOS disk** refers to either a DOS partition on a hard disk or a DOS floppy diskette.

You can download Mtools from the Mtools home page (mtools.linux.lu) or from rpmfind.net.

If the local kernel is configured to support DOS filesystems, you can mount DOS disks on a Linux filesystem and manipulate the files using Linux utilities. Although this feature is handy and reduces the need for Mtools, it may not be practical or efficient to mount and unmount DOS filesystems each time you need to access a DOS file. These tasks can be time-consuming, and some systems are set up so that regular users cannot mount and unmount filesystems.

Use caution when using Mtools. These utilities may not warn you if you are about to overwrite a file. Using explicit pathnames—not ambiguous file references—reduces the chance of overwriting a file.

The most common uses of the Mtools utilities are to examine files on DOS floppy diskettes (**mdir**) and to copy files between a DOS floppy diskette and the Linux filesystem (**mcopy**). You can identify DOS disks by using the usual DOS drive letters: **A:** for the first floppy drive, **C:** for the first hard disk, and so on. You can separate filenames in paths by using either the Linux forward slash (**/**) or the DOS backslash (**\**). You need to escape backslashes to prevent the shell from interpreting it before passing the pathname to the utility you are using.

Each of the Mtools utilities returns an exit code of 0 on success, 1 on complete failure, and 2 on partial failure.

Examples

In the first example, **mdir** displays the contents of a DOS floppy diskette in **/dev/fd0**:

```
$ mdir

Volume in drive A is DOS UTY
Directory for A:

ACAD     LIF      419370    5-10-05   1:29p

</table>

15 File(s) 599040 bytes free

The next example uses `mcopy` to copy the `*.TXT` files from the DOS floppy diskette to the working directory on the Linux filesystem. Because only one file has the extension `.TXT`, only one file is copied. Because `.TXT` files are usually text files under DOS, the `-t` option strips off the unnecessary RETURN characters at the end of each line. The ambiguous file reference `*` is escaped on the command line to prevent the shell from attempting to expand it before passing the argument to `mcopy`. The `mcopy` utility locates the file `README.TXT` when given the pattern `*.txt` because DOS does not differentiate between uppercase and lowercase letters in filenames.

```
$ mcopy -t a:\*.txt .

Copying README.TXT
```

Finally, the DOS floppy diskette is reformatted using `mformat`, wiping all data from the diskette. If the diskette has not been low-level formatted, you need to use `fdformat` before giving the following commands:

```
$ mformat a:

A check with `mdir` shows the floppy diskette is empty after formatting:

```
$ mdir a:

Volume in drive A has no label

Directory for A: /

File "*" not found
```

`mv`: Renames or moves a file

```
mv [options] existing-file new-filename
```
mv [options] existing-file-list directory
mv [options] existing-directory new-directory

The `mv` utility, which renames or moves one or more files, has three formats. The first renames a single file with a new filename that you supply. The second renames one or more files so that they appear in a specified directory. The third renames a directory. The `mv` utility physically moves the file if it is not possible to rename it (that is, if you move the file from one filesystem to another).

Arguments

In the first form, the `existing-file` is a pathname that specifies the ordinary file that you want to rename. The `new-filename` is the new pathname of the file.

In the second form, the `existing-file-list` is a list of the pathnames of the files that you want to rename and the `directory` specifies the new parent directory for the files. The files you rename will have the same simple filenames as each of the files in the `existing-file-list` but new absolute pathnames.

The third form renames the `existing-directory` with the `new-directory` name. This form works only when the `new-directory` does not already exist.

Options

Accepts the common options described on page 587.

- `backup`/`b` Makes a backup copy (by appending ~ to the filename) of any file that would be overwritten.
- `force`/`f` Causes `mv` not to prompt you if a move would overwrite an existing file that you do not have write permission for. You must have write permission for the directory holding the target file.
- `interactive`/`i` Prompts you for confirmation if `mv` would overwrite a file. If your response begins with a `y` or `Y`, `mv` overwrites the file; otherwise, `mv` does not move the file.
- `update`/`u` If a move would overwrite an existing file, not a directory, this option causes `mv` to compare the modification times of the source and target files. If the target file has a more recent modification time (the target is newer than the source), `mv` does not replace it.
- `verbose`/`v` Lists files as they are moved.

Notes

GNU `mv` is implemented as `cp` (with the `a` option) and `rm`. When you execute the `mv` utility, it first copies the `existing-file` to the `new-file`. It then deletes the `existing-file`. If the `new-file` already exists, `mv` may delete it before copying.

As with `rm`, you must have write and execute permission to the parent directory of the `existing-file`, but you do not need read or write access permission to the file itself. If the move would overwrite a file that you do not have write permission for, `mv` displays the file's access permissions and waits for a response. If you enter `y` or `Y`, `mv` overwrites the file; otherwise, it does not move the file. If you use the `f` option, `mv` does not prompt you for a response but simply overwrites the file.

Although earlier versions of `mv` could move only ordinary files between filesystems, `mv` can now move any type of file, including directories and device files.
Examples

The first command renames `letter`, a file in the working directory, as `letter.1201`:

```
$ mv letter letter.1201
```

The next command renames the file so that it appears, with the same simple filename, in the user's `~/.archives` directory:

```
$ mv letter.1201 ~/.archives
```

The following command moves all files in the working directory whose names begin with `memo` so they appear in the `/p04/backup` directory:

```
$ mv memo* /p04/backup
```

Using the `-u` option prevents `mv` from replacing a newer file with an older one. After the `mv -u` command shown below, the newer file, `memo2`, has not been overwritten. The `mv` command without the `-u` option overwrites the newer file (`memo2`'s modification time and size have changed to those of `memo1`).

```
$ ls -l
-rw-rw-r--  1 sam sam 22 Mar 25 23:34 memo1
-rw-rw-r--  1 sam sam 19 Mar 25 23:40 memo2
$ mv -u memo1 memo2
$ ls -l
-rw-rw-r--  1 sam sam 22 Mar 25 23:34 memo1
-rw-rw-r--  1 sam sam 19 Mar 25 23:40 memo2
```

```
$ mv memo1 memo2
$ ls -l
-rw-rw-r--  1 sam sam 22 Mar 25 23:34 memo2
```

nice: Changes the priority of a command

```
nice [option] [command-line]
```

The `nice` utility reports the priority of the shell or alters the priority of a command. An ordinary user can decrease the priority of a command. Only Superuser can increase the priority of a command. The TC Shell has a `nice` builtin that has a different syntax. Refer to "Notes" for more information.
Arguments

The **command-line** is the command line you want to execute at a different priority. Without any options or arguments, **nice** displays the priority of the shell running **nice**.

Options

Without an option, **nice** defaults to an adjustment of 10, lowering the priority of the command by 10—typically from 0 to 10. As you raise the priority value, the command runs at a lower priority.

\[\text{adjustment=}value\]

\[n\text{ value}\]

Changes the priority by the increment (or decrement) specified by **value**. The range of priorities is from \([-20\) (the highest priority) to 19 (the lowest priority). A positive **value** lowers the priority, whereas a negative **value** raises the priority. Only Superuser can specify a negative **value**. When you specify a value outside this range, the priority is set to the limit of the range.

Notes

You can use **top**'s **r** command (page 799) to change the priority of a running process.

Higher (more positive) priority values mean that the kernel schedules a job less often. Lower (more negative) values cause the job to be scheduled more often.

When Superuser schedules a job to run at the highest priority, this change can affect the performance of the system for all other jobs, including the operating system itself. For this reason you should be careful when using **nice** with negative values.

The TC Shell has a **nice** builtin. Under **tcsh**, use the following syntax to change the priority at which **command-line** is run. The default priority is 4. You must include the plus sign for positive values.

**nice** [±value] command line

Examples

The following command executes **find** in the background at the lowest possible priority. The **ps -l** command displays the **nice** value of the command in the **NI** column:

```
# nice -n 19 find / -name core -print > corefiles.out &
[1] 2610
# ps -l
  F S  UID  PID PPID  C PRI NI ADDR    SZ WCHAN TTY     TIME CMD
```
The next command finds very large files and runs at a high priority (15):

```bash
# nice -n -15 find / -size +50000k
```

nohup: Runs a command that keeps running after you log out

**nohup command line**

The nohup utility executes a command line such that the command keeps running after you log out. In other words, nohup causes a process to ignore a SIGHUP signal. Depending on how the shell is configured, it may kill your background processes when you log out. The TC Shell has a nohup builtin. Refer to "Notes" for more information.

**Arguments**

The command line is the command line you want to execute.

**Notes**

Accepts the common options described on page 587.

If you do not redirect the output from a command that you execute using nohup, both standard output and standard error are sent to the file named nohup.out in the working directory. If you do not have write permission for the working directory, nohup sends output to ~/nohup.out.

Unlike the nohup utility, the TC Shell's nohup builtin does not send output to nohup.out. Background jobs started from tcsh continue to run after you log out.

**Examples**

The following command executes find in the background, using nohup:

```bash
$ nohup find / -name core -print > corefiles.out &
```

[1] 14235

od: Dumps the contents of a file
od [options] [file-list]

The `od` (octal dump) utility dumps the contents of a file. The dump is useful for viewing executable (object) files and text files with embedded nonprinting characters. This utility takes its input from the file you specify on the command line or from standard input.

Arguments

The `file-list` specifies the pathnames of the files that `od` displays. When you do not specify a `file-list`, `od` reads from standard input.

Options

Accepts the common options described on page 587.

- `address radix=base`
  - A base
    - Specifies the base used when displaying the offsets shown for positions in the file. By default offsets are given in octal. Possible values for `base` are `d` (decimal), `o` (octal), `x` (hexadecimal), and `n` (no offsets printed).
  - `skip-bytes= n`  
    - Skips `n` bytes before displaying data.
  - `read-bytes= n`  
    - Reads a maximum of `n` bytes and quits.
  - `strings= n`  
    - Outputs from the file only those bytes that contain runs of `n` or more printable ASCII characters that are terminated by a NULL byte. The default value for `n` is 3.
  - `format= type [ n ]`
    - Specifies the output format to use when displaying data from a file. You can repeat this option with different format `type` s to see the file in several different formats. Table V-19 lists the possible values for `type`. By default `od` dumps a file as 2-byte octal numbers. You can specify the number of bytes `od` uses to compose each number by specifying a length indicator, `n`. You can specify a length indicator for all types except `a` and `c`. Table V-21 lists the possible values of `n`.

<table>
<thead>

Examples

The file ac, used in the following examples, contains all the ASCII characters. In the first example, the bytes in this file are displayed as named characters. The first column shows the offset of each byte from the start of the file. The offsets are given as octal values.

```
$ od -t a ac

0000000 nul soh stx etx eot enq ack bel bs ht nl vt ff cr so si
0000020 dle dc1 dc2 dc3 dc4 nak syn etb can em sub esc fs gs rs us
0000040 sp ! " # $ % & ' ( ) * + , - . / 0 1 2 3 4 5 6 7 8 9 : ; < = > ?
0000100 @ A B C D E F G H I J K L M N O
0000120 P Q R S T U V W X Y Z [ \ ] ^ _
0000140 \ a b c d e f g h i j k l m n o
0000160 p q r s t u v w x y z { | } ~ del
0000200 nul soh stx etx eot enq ack bel bs ht nl vt ff cr so si
0000220 dle dc1 dc2 dc3 dc4 nak syn etb can em sub esc fs gs rs us
0000240 sp ! " # $ % & ' ( ) * + , - . / 0 1 2 3 4 5 6 7 8 9 : ; < = > ?
0000260 @ A B C D E F G H I J K L M N O
0000300 P Q R S T U V W X Y Z [ \ ] ^ _
0000340 \ a b c d e f g h i j k l m n o
0000360 p q r s t u v w x y z { | } ~ del
0000400 nl
```

0000401
In the next example, the bytes are displayed as octal numbers, ASCII characters, or printing characters preceded by a backslash (refer to Table V-20 on page 738):

```
$ od -t c ac
0000000 \0 001 002 003 004 005 006 \a \b \t \n \v \f \r 016 017

0000400 \n
0000401
```

The final example finds in the file `/usr/bin/who` all strings that are at least three characters long (the default) and terminated by a null byte. See `strings` on page 777 for another way of displaying a similar list. The offset positions are given as decimal offsets instead of octal offsets.

```
$ $ od -A d --strings /usr/bin/who
...
```
paste: Joins corresponding lines from files

paste [option] [file-list]

The **paste** utility reads lines from the **file-list** and joins corresponding lines in its output. By default output lines are separated by a TAB character.

**Arguments**

The **file-list** is a list of ordinary files. When you omit the **file-list**, **paste** reads from standard input.

**Options**
Accepts the common options described on page 587.

`delimiter=dlist`

The `dlist` is a list of characters to be used to separate output fields. If `dlist` contains a single character, `paste` uses that character instead of the default TAB character to separate fields. If `dlist` contains more than one character, the characters are used in turn to separate output lines and are then reused from the beginning of the list as necessary.

`serial` is Processes one file at a time; pastes horizontally. See "Examples."

Notes

A common use of `paste` is to rearrange the columns of a table. A utility, such as `cut`, can place the desired columns in separate files, and then `paste` can join them in any order.

Examples

The following example uses the files `fnames` and `acctinfo`. These files can easily be created by using `cut` (page 627) and the `/etc/passwd` file. The `paste` command puts the full-name field first, followed by the remaining user account information. A TAB character separates the two output fields.

```
$ cat fnames
Jenny Chen
Alex Watson
Scott Adams
Helen Simpson

$ cat acctinfo
jenny:x:401:50:/home/jenny:/bin/zsh
alex:x:402:50:/home/alex:/bin/bash
scott:x:504:500:/home/scott:/bin/tcsh
hls:x:505:500:/home/hls:/bin/bash

$ paste fnames acctinfo
```
The next examples use the files \texttt{p1}, \texttt{p2}, \texttt{p3}, and \texttt{p4}. The last example in this group uses the \texttt{--delimiter} option to give \texttt{paste} a list of characters to use to separate output fields:

\begin{verbatim}
$ cat p1
1
one
ONE
$ cat p2
2
two
TWO
extra
$ cat p3
3
three
THREE
$ cat p4
4
four
FOUR

$ paste p4 p3 p2 p1
4     3     2     1
four  three  two  one
\end{verbatim}
$ paste --delimiter="+-=" p3 p2 p1 p4

3+2-1=4
three+two-one=four
THREE+TWO-ONE=FOUR
+extra= 

The final example uses the **serial** option to paste the files one at a time:

$ paste --serial p1 p2 p3 p4

1       one     ONE
2       two     TWO     extra
3       three   THREE
4       four    FOUR

**pr: Paginates files for printing**

**pr [options] [file-list]**

The **pr** utility breaks files into pages, usually in preparation for printing. Each page has a header with the name of the file, date, time, and page number.

The **pr** utility takes its input from files you specify on the command line or from standard input. The output from **pr** goes to standard output and is frequently redirected by a pipe to a printer.

**Arguments**

The **file-list** is a list of the pathnames of text files that you want **pr** to paginate. When you omit the **file-list**, **pr** reads from standard input.

**Options**

Accepts the **common options** described on page 587.
You can embed options within the `file-list`. An embedded option affects only those files following it on the command line.

**show-control-chars**

- `c` Displays control characters with a caret (^; for example, ^H). Displays other nonprinting characters as octal numbers preceded by a backslash.

**columns= col  col**

Displays output in `col` columns with a default of one. This option may truncate lines and cannot be used with the `merge` option.

**double-space d**

Double-spaces the output.

**form-feed f**

Uses a FORMFEED character to skip to the next page rather than filling the current page with NEWLINE characters.

**header= head  head**

Displays `head` at the top of each page instead of the filename. If `head` contains SPACE s, you must enclose it within quotation marks.

**length= lines  l lines**

Sets the page length to `lines` lines. The default is 66 lines.

**merge m**

Displays all specified files simultaneously in multiple columns. This option cannot be used with `columns`.

**number-lines=[c[num]]**

- `n [ c [ num ] ]`

  Numbers the lines of output. The `c` is a character that `pr` appends to the number to separate it from the contents of the file (the default is a TAB). The `num` specifies the number of digits in each line number (the default is 5).

**indent= spaces  o spaces**

Indents the output by `spaces` characters (specifies the left margin).

**separator= c  s[c]**

Separates columns with the single character `c` (defaults to TAB when you omit `c`). By default `pr` uses TAB s as separation characters to align columns unless you use the `w` option, in which case nothing separates columns.

**omit-header t**

Causes `pr` not to display its five-line page header and trailer. The header that `pr` normally displays includes the name of the file, the date, time, and page number. The trailer is five blank lines.

**width= num  w num**

Sets the page width to `num` columns. This option is effective only with multicolumn output (the `merge` or `columns` option).

**firstpage[:lastpage]**

- `+ firstpage [:lastpage ]`

  Output begins with the page numbered `firstpage` and ends with `lastpage`. Without `lastpage`, `pr` outputs through the last page of the document. The short version of this option begins with a plus sign, not a hyphen.
Notes

When you use the `columns` option to display the output in multiple columns, `pr` displays the same number of lines in each column (with the possible exception of the last).

Examples

The first command shows `pr` paginating a file named `memo` and sending its output through a pipe to `lpr` for printing:

```
$ pr memo | lpr
```

Now `memo` is sent to the printer again, this time with a special heading at the top of each page. The job is run in the background.

```
$ pr -h 'MEMO RE: BOOK' memo | lpr &
[1] 4904
```

Next `pr` displays the `memo` file on the screen, without any header, starting with page 3:

```
$ pr -t +3 memo
...
```

**ps: Displays process status**

`ps [options] [process-list]`

The `ps` utility displays status information about processes running on the local system.

Arguments

The `process-list` is a comma- or SPACE-separated list of PID numbers. When you specify a `process-list`, `ps` reports on just the processes in that list.

Options

The `ps` utility accepts three types of options, each preceded by a different prefix. You can intermix the options.

Two hyphens: GNU (long) options
One hyphen: UNIX98 (short) options
No hyphens: BSD options
A (all) Reports on all processes. Also $e$.
$e$ (everything) Reports on all processes. Also $A$.
$R$ (full) Displays a listing with more columns of information.
$A$forest Displays the process tree.
$A$ (long) Produces a long listing showing more information about each process. See the "Discussion" section for a description of all the columns that this option displays.
$A$no-headers Omits the header. This option is useful if you are sending the output to another program for further processing.
$A$user-oriented Adds to the display the username of the user running the process, the time the process was started, the percentage of CPU and memory the process is using, and other information.

$A$User=username Reports on processes being run by username, which can be the name or UID of a user on the local system.
$A$w (wide) Without this option $ps$ truncates output lines at the right side of the screen. This option extends the display so it wraps around one more line, if needed.

Discussion

Without any options, $ps$ displays the statuses of all active processes that your terminal/screen controls. Table V-23 lists the heading and content of each of the four columns that $ps$ displays.

<table>
<thead>
<tr>
<th>Heading</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>PID</td>
<td>The process identification number.</td>
</tr>
<tr>
<td>TTY (terminal)</td>
<td>The name of the terminal that controls the process.</td>
</tr>
<tr>
<td>TIME</td>
<td>The number of hours, minutes, and seconds the process has been running.</td>
</tr>
<tr>
<td>CMD</td>
<td>The command line the process was called with. The command is truncated to fit on one line. Use the $w$ option to see more of the command line.</td>
</tr>
</tbody>
</table>

The columns that $ps$ displays depend on your choice of options. Table V-24 lists the headings and contents of the most common columns.

<table>
<thead>
<tr>
<th>Heading</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>%CPU</td>
<td>The percentage of total CPU time that the process is using. Owing to the way that Linux handles process accounting, this figure is approximate, and the total of %CPU values for all processes may exceed 100%.</td>
</tr>
<tr>
<td>%MEM (memory)</td>
<td>The percentage of RAM that the process is using.</td>
</tr>
<tr>
<td>COMMAND or CMD</td>
<td>The command line the process was called with. The command is truncated to fit</td>
</tr>
</tbody>
</table>
The column titles differ, depending on the type of option you use. This table shows the headings for UNIX98 (one-hyphen) options.

<table>
<thead>
<tr>
<th>Heading</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>F (flags)</strong></td>
<td>The flags associated with the process.</td>
</tr>
<tr>
<td><strong>PID</strong></td>
<td>The process identification number.</td>
</tr>
<tr>
<td><strong>PPID</strong> (parent PID)</td>
<td>The process identification number of the parent process.</td>
</tr>
<tr>
<td><strong>PRI</strong> (priority)</td>
<td>The priority of the process.</td>
</tr>
<tr>
<td><strong>RSS</strong> (resident set size)</td>
<td>The number of blocks of memory that the process is using.</td>
</tr>
<tr>
<td><strong>SIZE or SZ</strong></td>
<td>The size, in blocks, of the core image of the process.</td>
</tr>
<tr>
<td><strong>STIME or START</strong></td>
<td>The date the process started.</td>
</tr>
<tr>
<td><strong>STAT or S</strong> (status)</td>
<td>The status of the process as specified by one or more letters from the following list:</td>
</tr>
<tr>
<td></td>
<td>&lt;</td>
</tr>
<tr>
<td></td>
<td>D</td>
</tr>
<tr>
<td></td>
<td>L</td>
</tr>
<tr>
<td></td>
<td>N</td>
</tr>
<tr>
<td></td>
<td>R</td>
</tr>
<tr>
<td></td>
<td>S</td>
</tr>
<tr>
<td></td>
<td>T</td>
</tr>
<tr>
<td></td>
<td>W</td>
</tr>
<tr>
<td></td>
<td>X</td>
</tr>
<tr>
<td></td>
<td>Z</td>
</tr>
<tr>
<td><strong>TIME</strong></td>
<td>The number of minutes and seconds that the process has been running.</td>
</tr>
<tr>
<td><strong>TTY</strong> (terminal)</td>
<td>The name of the terminal controlling the process.</td>
</tr>
<tr>
<td><strong>USER or UID</strong></td>
<td>The username of the user who owns the process.</td>
</tr>
<tr>
<td><strong>WCHAN</strong> (wait channel)</td>
<td>If the process is waiting for an event, the address of the kernel function that caused the process to wait. It is 0 for processes that are not waiting or sleeping.</td>
</tr>
</tbody>
</table>

**Notes**

Use `top` (page 798) to display process status information dynamically.

**Examples**

The first example shows `ps`, without any options, displaying the user's active processes. The first process is the shell (`bash`), and the second is the process executing the `ps` utility.

```bash
$ ps
```
With the `l` (long) option, `ps` displays more information about the processes:

```
$ ps -l
```

<p>| | | | | | | | | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>F S</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>USER</td>
<td>PID</td>
<td>PPID</td>
<td>C</td>
<td>PRI</td>
<td>NI</td>
<td>ADDR</td>
<td>SZ</td>
<td>WCHAN</td>
<td>TTY</td>
<td>TIME</td>
<td>CMD</td>
<td></td>
</tr>
<tr>
<td>alex</td>
<td>2697</td>
<td>2696</td>
<td>0</td>
<td>75</td>
<td>0</td>
<td>-</td>
<td>639</td>
<td>wait4</td>
<td>pts/0</td>
<td>00:00:02</td>
<td>bash</td>
<td></td>
</tr>
<tr>
<td>alex</td>
<td>3303</td>
<td>2697</td>
<td>0</td>
<td>76</td>
<td>0</td>
<td>-</td>
<td>744</td>
<td>-</td>
<td>pts/0</td>
<td>00:00:00</td>
<td>ps</td>
<td></td>
</tr>
</tbody>
</table>

The `u` option shows various types of information about the processes, including how much of the local system CPU and memory each one is using:

```
$ ps -u
```

<table>
<thead>
<tr>
<th>USER</th>
<th>PID</th>
<th>%CPU</th>
<th>%MEM</th>
<th>VSZ</th>
<th>RSS</th>
<th>TTY</th>
<th>STAT</th>
<th>START</th>
<th>TIME</th>
<th>COMMAND</th>
</tr>
</thead>
<tbody>
<tr>
<td>alex</td>
<td>2697</td>
<td>0.0</td>
<td>0.5</td>
<td>2556</td>
<td>1460</td>
<td>pts/0</td>
<td>S</td>
<td>Jul31</td>
<td>0:02</td>
<td>-bash</td>
</tr>
<tr>
<td>alex</td>
<td>3303</td>
<td>0.0</td>
<td>0.2</td>
<td>2476</td>
<td>616</td>
<td>pts/0</td>
<td>R</td>
<td>Jul31</td>
<td>0:00</td>
<td>ps -u</td>
</tr>
</tbody>
</table>

The `forest` option causes `ps` to display what the `man` page describes as an "ASCII art process tree." Processes that are children of other processes appear indented under their parents, making the process hierarchy, or tree, easier to see.

```
$ ps -ef --forest
```

<table>
<thead>
<tr>
<th>UID</th>
<th>PID</th>
<th>PPID</th>
<th>C</th>
<th>STIME</th>
<th>TTY</th>
<th>TIME</th>
<th>CMD</th>
</tr>
</thead>
<tbody>

<td>839</td>
<td>0</td>
<td>Aug01</td>
<td>?</td>
<td>00:00:00</td>
<td>_ /usr/sbin/sshd</td>
</tr>
</tbody>
</table>
ps and kill

The next sequence of commands shows how to use `ps` to determine the PID number of a process running in the background and how to terminate that process by using the `kill` command. In this case it is not necessary to use `ps` because the shell displays the PID number of the background processes. The `ps` utility verifies the PID number.

The first command executes `find` in the background. The shell displays the job and PID numbers of the process, followed by a prompt.

```bash
$ find ~ -name memo -print > memo.out &
[1] 3343
```

Next `ps` confirms the PID number of the background task. If you did not already know this number, using `ps` would be the only way to find it out.

```bash
$ ps
   PID TTY       TIME CMD
 3308 pts/1   00:00:00 bash
 3343 pts/1   00:00:00 find
```
Finally kill (page 693) terminates the process:

$ kill 3343
$ RETURN

[1]+ Terminated find ~ -name memo -print >memo.out
$

cp: Copies one or more files to or from a remote system

`rcp [options] source-file destination-file`
`rcp [options] source-file-list destination-directory`

The `rcp` utility copies one or more ordinary files between two systems that can communicate over a network.

**security: rcp is not secure**

The `rcp` utility uses host-based trust, which is not secure, to authorize files to be copied. Use `scp` (page 758) when it is available.

**Arguments**

The `source-file`, `source-file-list`, and `destination-file` are pathnames of the ordinary files, and the `destination-directory` is the pathname of a directory file. A pathname that does not contain a colon (:) is the name of a file on the local system. A pathname of the form `name @ host: path` names a file on the remote system named `host`. The `path` is relative to the home directory of the user `name` (unless `path` is an absolute pathname). When you omit the `name @` portion of the destination, a relative pathname is relative to the home directory on the `host` of the user giving the `rcp` command.

Like `cp`, `rcp` has two modes of operation: The first copies one file to another, and the second copies one or more files to a directory. The `source-file [ -list ]` is a list of the name(s) of the file(s) that `rcp` will copy; `destination-file` is the name that `rcp` assigns to the resulting copy of the file, or `destination-directory` is the name of the directory that `rcp` puts the copied files in. When `rcp` copies files to a `destination-directory`, the files maintain their original simple filenames.

**Options**

`-p (preserve)` Sets the modification times and file access permissions of each copy to match those of the `source-file`. When you do not use `-p`, `rcp` uses the file-creation mask (umask; see page 810) on the remote system to modify the access permissions.

`-r (recursive)` When a file in the `source-file-list` is a directory, copies the contents of that directory and any subdirectories into the `destination-directory`. You can use this option only when the destination is a directory.
You must have an account on the remote system to copy files to or from it using rcp. The rcp utility does not prompt for a password but uses several alternative methods to verify that you have the authority to read or write files on the remote system.

One method requires that the name of the local system be specified in the /etc/hosts.equiv file on the remote system. If the name is there, rcp allows you to copy files if your usernames are the same on both systems and your account on the remote system has the necessary permissions to access files there.

Authorization can also be specified on a per-user basis. Using this method the remote user's home directory must contain a file named ~/.rhosts that lists trusted remote systems and users. With this method, your local and remote user names do not have to match but your local username must appear on the line in the remote ~/.rhosts file that starts with the name of the local system. See "Examples" for rlogin (page 752) for a sample .rhosts file.

If you use a wildcard (such as *) in a remote pathname, you must quote the wildcard character or pathname so that the wildcard is interpreted by the shell on the remote system and not by the local shell. As with cp, if the destination-file exists before you execute rcp, rcp overwrites the file.

Examples

The first example copies the files with filenames ending in .c into the archives directory on the remote system named bravo. Because a username is not specified, rcp uses the local user's username on the remote system. Because the full pathname of the archives directory is not specified, rcp assumes that it is a subdirectory of the user's home directory on bravo. Each of the copied files retains its simple filename.

$ rcp *.c bravo:archives

The next example copies memo from the /home/jenny directory on bravo to the working directory on the local system:

$ rcp bravo:/home/jenny/memo .

Next rcp copies the files named memo.new and letter to Jenny's home directory on the remote system bravo. The absolute pathnames of the copied files on bravo are /home/jenny/memo.new and /home/jenny/letter:

$ rcp memo.new letter bravo:/home/jenny

The final command copies all the files in Jenny's reports directory on bravo to the oldreports directory on the local system, preserving the original modification dates and file access permissions on the copies:

$ rcp -p 'bravo:reports/*' oldreports

rlogin: Logs in on a remote system

rlogin [option] remote-system
The `rlogin` utility establishes a login session on a remote system over a network.

**security: rlogin is not secure**

The `rlogin` utility uses host-based trust, which is not secure, to authorize your login. Alternatively, it sends your password over the network as cleartext, which is not a secure practice. Use `ssh` (page 773) when it is available.

**Arguments**

The `remote-system` is the name of a system that the local system can reach over a network.

**Options**

`-l username` *(login)* Logs you in on the remote system as the user specified by `username`.

**Notes**

If the file named `/etc/hosts.equiv` located on the remote system specifies the name of the local system, the remote system will not prompt you to enter your password. Systems that are listed in the `/etc/hosts.equiv` file are considered as secure as the local system.

An alternative way to specify a trusted relationship is on a per-user basis. Each user's home directory can contain a file named `~/.rhosts` that holds a list of trusted remote systems and users. See "Examples" for a sample `.rhosts` file.

**Examples**

The following example illustrates the use of `rlogin`. On the local system, Alex's username is `alex`; on the remote system `bravo`, his username is `watson`. The remote system prompts Alex to enter a password because he is logging in using a username different from the one he uses on the local system.

```
$ who am i
alex       tty06         Oct 14 13:26

$ rlogin -l watson bravo
Password:
```

`~/.rhosts` file

If the local system is named `hurrah`, the following `.rhosts` file on `bravo` allows the user `alex` to log in as the user `watson` without entering a password:

```
```
$ cat /home/watson/.rhosts

hurrah alex

**rm**: Removes a file (deletes a link)

```
rm [options] file-list
```

The `rm` utility removes hard and/or symbolic links to one or more files. When you remove the last hard link to a file, the file is deleted.

**caution: Be careful when you use rm with wildcards**

Because you can remove a large number of files with a single command, use `rm` cautiously, especially when you are working with ambiguous file references. If you have doubts about the effect of an `rm` command with an ambiguous file reference, first use `echo` with the same file reference and evaluate the list of files the reference generates. Alternatively, you can use the `interactive` option.

**Arguments**

The **file-list** is a list of the list of files that `rm` deletes.

**Options**

Accepts the **common options** described on page 587.

- `force`  
  `-f` Without asking for your consent, removes files for which you do not have write access permission. This option also suppresses informative output if a file does not exist.

- `interactive`  
  `-i` Asks before removing each file. If you use `recursive` with this option, `rm` also asks you before examining each directory.

- `recursive`  
  `-r` Deletes the contents of the specified directory, including all its subdirectories, and the directory itself. Use this option cautiously.

- `verbose`  
  `-v` Displays the name of each file as it is removed.

**Notes**

To delete a file, you must have execute and write access permission to the parent directory of the file, but you do not need read or write access permission to the file itself. If you are running `rm` interactively (that is, if `rm`'s standard input is coming from the keyboard) and you do not have write access permission to the file, `rm` displays your access permission and waits for you to respond. If your response starts with a `y` or `Y`, `rm` deletes the file; otherwise, it takes no action. If standard input is not coming from a keyboard, `rm` deletes the file without question.

Refer to page 97 for information on **hard links** and page 99 for information on **symbolic links**. Page 101 includes a discussion about **removing links**. Refer to the `rmdir` utility (page 755) if you need to remove an empty directory.

When you want to remove a file that begins with a hyphen, you must prevent `rm` from interpreting the filename as an option. One way to do so is to give the special option `-i` before the name of the file. This option tells `rm` that no
more options follow: Any arguments that come after it are filenames, even if they look like options.

**security: Use shred to remove a file securely**

Using `rm` does not securely delete a file; it is possible to recover a file deleted with `rm`. Use the shred utility to delete files more securely. See the example "Wiping a file" on page 634 for another method of deleting files more securely.

**Examples**

The following commands delete files both in the working directory and in another directory:

```
$ rm memo
$ rm letter memo1 memo2
$ rm /home/jenny/temp
```

The next example asks the user before removing each file in the working directory and its subdirectories:

```
$ rm -ir .
```

This command is useful for removing filenames that contain special characters, especially SPACEs, TABs, and NEWLINEs. (You should not create filenames containing these characters on purpose, but it may happen accidentally.)

**rmdir: Removes a directory**

```
rmdir directory-list
```

The `rmdir` utility deletes empty directories.

**Arguments**

The `directory-list` is a list of pathnames of empty directories that `rmdir` removes.

**Options**

Accepts the common options described on page 587.

- `ignore-fail-on-non-empty` Suppresses the message `rmdir` normally displays when it fails because a directory is not empty.

- `parents -p` Removes a series of empty, nested directories, starting with the child.
verbose
Displays the names of directories as they are removed.

Notes

Use the `rm` utility with the `-r` option if you need to remove directories that are not empty, together with their contents.

Examples

The following command deletes the empty `literature` directory from the working directory:

```bash
$ rmdir literature
```

The next command removes the `letters` directory, using an absolute pathname:

```bash
$ rmdir /home/jenny/letters
```

The final command removes the `letters`, `march`, and `05` directories, assuming the directories are empty except for other directories named in the path:

```bash
$ rmdir --parents letters/march/05
```

rsh: Executes commands on a remote system

```bash
rsh [option] host [command-line]
```

The `rsh` utility runs `command-line` on `host` by starting a shell on the remote system. Without a `command-line` `rsh` calls `rlogin`, which logs you in on the remote system.

security: `rsh` is not secure

The `rsh` utility uses host-based trust, which is not secure, to authorize your login. Alternatively, it sends your password over the network as cleartext, which is not a secure practice. Use `ssh` (page 773) when it is available.

Arguments

The `host` is the name of the remote system. The `rsh` utility runs `command-line` on the remote system. You must quote special characters in `command-line` so that they are not expanded by the local shell prior to passing them to `rsh`.

Options

- `-l username` (login) Logs you in on the remote system as the user specified by `username`. 
Notes

If the file named `/etc/hosts.equiv` located on the remote system specifies the name of the local system, the remote system will not prompt you to enter your password. Systems that are listed in the `/etc/hosts.equiv` file are considered as secure as the local system.

An alternative way to specify a trusted relationship is on a per-user basis. Each user's home directory can contain a file named `~/.rhosts` that holds a list of trusted remote systems and users. See "Examples" under `rlogin` (page 752) for a sample `.rhosts` file.

Examples

In the first example, Alex uses `rsh` to obtain a listing of the files in his home directory on `bravo`:

```
$ rsh bravo ls

cost_of_living
info
preferences
work
```

Next the output of the previous command is redirected into the file `bravo.ls`. Because the redirection character (`>`) is not escaped, it is interpreted by the local shell, and the file `bravo.ls` is created on the local system.

```
$ rsh bravo ls > bravo_ls
$ cat bravo_ls

cost_of_living
info
preferences
work
```

The next example quotes the redirection character (`>`) so that the file `bravo.ls` is created on the remote system (`bravo`), as shown by `ls` run on `bravo`:

```
$ rsh bravo ls "">" bravo.ls
$ rsh bravo ls
bravo.ls
```
In the final example, `rsh` without `command-line` logs in on the remote system. Alex has used the `ll watson` option to log in on `bravo` as `watson`. The `/home/watson/.rhosts` file must be configured to allow Alex to log in on the account in this manner. See "Examples" under `rlogin` (page 752) for a sample `.rhosts` file.

```
$ rsh -l watson bravo
Last login: Sat Jul 30 16:13:53 from kudos
$ hostname
bravo
$ exit
rlogin: connection closed.
```

**scp: Securely copies one or more files to or from a remote system**

```
scp [[user@[from-host:]source-file [[user@[to-host:]][destination-file]
```

The `scp` (secure copy) utility copies an ordinary or directory file from one system to another on a network. This utility uses `ssh` to transfer files and the same authentication mechanism as `ssh`; therefore it provides the same security as `ssh`. The `scp` utility asks you for a password when it is needed.

**Arguments**

The `from-host` is the name of the system you are copying files from and the `to-host` is the system you are copying to. When you do not specify a host, `scp` assumes the local system. The `user` on either system defaults to the user on the local system who is giving the command; you can specify a different user with `user@`. The `scp` utility permits you to copy between two remote systems.

The `source-file` is the file you are copying, and the `destination-file` is the resulting copy. You can specify plain or directory files as relative or absolute pathnames. A relative pathname is relative to the specified or implicit user’s home directory. When the `source-file` is a directory, you must use the `r` option to copy its contents. When the `destination-file` is a directory, each of the source files maintains its simple filename.

**Options**
preserve) Preserves the modification and access times as well as the permissions of the original file.

quiet) Does not display the progress meter.

recursive) Recursively copies a directory hierarchy.

verbose) Displays debugging messages about the connection and transfer. This option is useful if things are not going as expected.

Notes

The scp utility is one of the OpenSSH suite of secure network connectivity tools. See "Notes" on page 774 for a discussion of OpenSSH security. Refer to "Message on initial connection to a server" on page 774 for information about a message you may get when using scp to connect to a remote system for the first time.

You can copy from or to the local system or between two remote systems. Make sure that you have read permission for the file you are copying and write permission for the directory you are copying it into.

You must quote a wildcard character (such as *) in a remote pathname so that it is interpreted by the shell on the remote system and not by the local shell.

As with cp, if the destination-file exists before you run scp, scp overwrites the file.

Examples

The first example copies the files with filenames ending in .c from the working directory on the local system into the ~jenny/archives directory on bravo. The wildcard character is not quoted so that the local shell will expand it. Because archives is a relative pathname, scp assumes that it is a subdirectory of Jenny's home directory on bravo. Each of the copied files retains its simple filename.

$ scp *.c jenny@bravo:archives

Next Alex copies the directory structure under ~alex/memos on the system named bravo to ~jenny/alex.memos.bravo on kudos. He must have the necessary permissions to write to Jenny's home directory on kudos.

$ scp -r bravo:memos jenny@kudos:alex.memos.bravo

Finally Alex copies the files with filenames ending in .c from Jenny's archives directory on bravo to the jenny.c.bravo directory in his working directory. The wildcard character is quoted to protect it from expansion by the local shell; it will be interpreted by the remote system, bravo.

$ scp -r 'jenny@bravo:archives/*.c' jenny.c.bravo

It is important to remember that whenever you copy multiple files or directories, the destination—either local or remote—must be an existing directory and not an ordinary or nonexistent file.

sleep: Creates a process that sleeps for a specified interval
sleep time
sleep time-list

The `sleep` utility causes the process executing it to go to sleep for the time specified.

Arguments

Traditionally the amount of time that a process sleeps is given as a single integer argument, `time`, which denotes a number of seconds. The `time` does not have to be an integer, however: You can specify a decimal fraction. You can also append a unit specification to `time`: `s` (seconds), `m` (minutes), `h` (hours), and `d` (days).

You can construct a `time-list` by including several times on the command line: The total time that the process sleeps is the sum of these times. For example, if you specify `1h 30m 100s`, the process will sleep for 91 minutes and 40 seconds.

Examples

You can use `sleep` from the command line to execute a command after a period of time. The following example executes in the background a process that reminds you to make a phone call in 20 minutes (1,200 seconds):

```bash
$ (sleep 1200; echo "Remember to make call.") &
[1] 4660
```

Alternatively, you could give the following command to get the same reminder:

```bash
$ (sleep 20m; echo "Remember to make call.") &
[2] 4667
```

You can also use `sleep` within a shell script to execute a command at regular intervals. The `per` shell script executes a program named `update` every 90 seconds:

```bash
$ cat per
#!/bin/bash
while true
do
    update
    sleep 90
done
```
If you execute a shell script such as `per` in the background, you can terminate it only by using `kill`.

The final shell script accepts the name of a file as an argument and waits for that file to appear on the disk. If the file does not exist, the script sleeps for 1 minute and 45 seconds before checking for the file again:

```bash
$ cat wait_for_file
#!/bin/bash

if [ $# != 1 ]; then
    echo "Usage: wait_for_file filename"
    exit 1
fi

while true
do
    if [ -f "$1" ]; then
        echo "$1 is here now"
        exit 0
    fi
    sleep 1m 45
done
```

sort: Sorts and/or merges files

```bash
sort [options] [file-list]
```

The `sort` utility sorts and/or merges one or more text files.

Arguments

The `file-list` is a list of pathnames of one or more ordinary files that contain the text to be sorted. If the `file-list` is omitted, `sort` takes its input from standard input. Without the `o` option `sort` sends its output to standard output. This utility sorts and merges files unless you use the `m` (merge only) or `c` (check only) option.
Options

When you do not specify an option, `sort` orders the file in the machine collating sequence (usually ASCII).
Without a `key` option `sort` orders a file based on full lines. Use `key` to specify sort fields within a line. You can follow a `key` option with additional options without a leading hyphen; see "Discussion" for more information.

- **ignore-leading-blanks**
  - Blanks (TAB and SPACE characters) normally mark the beginning of fields in the input file. Without this option, `sort` considers leading blanks to be part of the field they precede. This option ignores leading blanks within a field, so `sort` does not consider these characters in sort comparisons.

- **check**
  - Checks whether the file is properly sorted. The `sort` utility does not display anything if everything is in order. It displays a message if the file is not in sorted order and returns an exit status of 1.

- **dictionary-order**
  - Ignores all characters that are not alphanumeric characters or blanks. For example, `sort` does not consider punctuation with this option.

- **ignore-case**
  - Considers all lowercase letters to be uppercase letters. Use this option when you are sorting a file that contains both uppercase and lowercase text.

- **ignore-nonprinting**
  - Ignores nonprinting characters. This option is overridden by the `dictionary-order` option.

- **key=start[,stop]**
  - Specifies a sort field within a line. Without this option `sort` orders a file based on full lines. The sort field starts at the position on the line specified by `start` and ends at `stop`, or the end of the line if `stop` is omitted. The `start` and `stop` positions are in the format `f[c]`, where `f` is the field number and `c` is the optional character within the field. Numbering starts with 1. When `c` is omitted from `start`, it defaults to the first character in the field; when `c` is omitted from `stop`, it defaults to the last character in the field. See "Discussion" for further explanation of sort fields and "Examples" for illustrations of their use.

- **merge**
  - Assumes that multiple input files are each in sorted order and merges them without verifying that they are sorted.

- **numeric-sort**
  - Sorts in arithmetic sequence; does not order lines or sort fields in the machine collating sequence. With this option, minus signs and decimal points take on their arithmetic meaning.

- **output=filename**
  - Sends output to `filename` instead of standard output; `filename` can be the same as one of the
names in the file-list.

- `reverse -r` Reverses the sense of the sort (for example, z precedes a).

- `field-separator=\x`

  \x

  Specifies \x as the field separator. See "Discussion" for more information.

- `unique -u` Outputs repeated lines only once. When you use this option with `check`, `sort` displays a message if the same line appears more than once in the input file, even if the file is in sorted order.

### Discussion

Without any **options** `sort` bases its ordering on full lines.

In the following description, a *field* is a sequence of characters in a line of input. Without the `field-separator` option, fields are bounded by the empty string preceding a group of one or more blanks (TAB and SPACE characters). You cannot see the empty string that delimits the fields; it is an imaginary point between two fields. Fields are also bounded by the beginning and end of the line. The line shown in Figure 0-1 holds the fields Toni, SPACE Barnett, and SPACESPACE SPACE55020. These fields are used to define sort fields. Sometimes fields and sort fields are the same.

#### Sort field

A *sort field* is a sequence of characters that `sort` uses to put lines in order. A sort field can contain all or part of one or more fields (Figure V-1).

### Figure V-1. Fields and sort fields

![Figure V-1](image)

The `key` option specifies pairs of pointers that define subsections of each line (sort fields) for comparison. See the `key` option (page 763) for details.

#### Leading blanks

The `b` option causes `sort` to ignore leading blanks in a sort field. If you do not use this option, `sort` considers each leading blank to be a character in the sort field and includes it in the sort comparison.

### Options
You can specify options that pertain only to a given sort field by immediately following the stop pointer (or the start pointer if there is no stop pointer) with one of the options b, d, f, i, n, or r. In this case you must not precede the option with a hyphen.

Multiple sort fields

When you specify more than one sort field, sort examines them in the order you specify them on the command line. If the first sort field of two lines is the same, sort examines the second sort field. If these are again the same, sort looks at the third field. This process continues for all the sort fields you specify. If all the sort fields are the same, sort examines the entire line.

Examples

The examples in this section demonstrate some of the features and uses of the sort utility. The examples assume that the list file shown here is in the working directory:

$ cat list
Tom Winstrom 94201
Janet Dempsey 94111
Alice MacLeod 94114
David Mack 94114
Toni Barnett 95020
Jack Cooper 94072
Richard MacDonald 95510

This file contains a list of names and ZIP codes. Each line of the file contains three fields: the first name field, the last name field, and the ZIP code field. For the examples to work, make sure the blanks in the file are SPACE s, and not TABs.

The first example demonstrates sort without any options—the only argument is the name of the input file. In this case sort orders the file on a line-by-line basis. If the first characters on two lines are the same, sort looks at the second characters to determine the proper order. If the second characters are the same, sort looks at the third characters. This process continues until sort finds a character that differs between the lines. If the lines are identical, it does not matter which one sort puts first. In this example, sort needs to examine only the first three characters (at most) of each line. The sort utility displays a list that is in alphabetical order by first name.

$ sort list
Alice MacLeod 94114
<table>
<thead>
<tr>
<th>Name</th>
<th>ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>David Mack</td>
<td>94114</td>
</tr>
<tr>
<td>Jack Cooper</td>
<td>94072</td>
</tr>
<tr>
<td>Janet Dempsey</td>
<td>94111</td>
</tr>
<tr>
<td>Richard MacDonald</td>
<td>95510</td>
</tr>
<tr>
<td>Tom Winstrom</td>
<td>94201</td>
</tr>
<tr>
<td>Toni Barnett</td>
<td>95020</td>
</tr>
</tbody>
</table>

You can instruct `sort` to skip any number of fields and characters on a line before beginning its comparison. Blanks normally mark the beginning of a field. The next example sorts the same list by last name, the second field. The `--key=2` argument instructs `sort` to begin its comparison with the second field, the last name. Because there is no second pointer, the sort field extends to the end of the line. Now the list is almost in last-name order, but there is a problem with Mac.

```
$ sort --key=2 list
Toni Barnett         95020
Jack Cooper          94072
Janet Dempsey        94111
Richard MacDonald    95510
Alice MacLeod        94114
David Mack           94114
Tom Winstrom         94201
```

In the preceding example, MacLeod comes before Mack. After finding that the sort fields of these two lines were the same through the third letter (Mac), `sort` put L before k because it arranges lines based on ASCII character codes, in which uppercase letters come before lowercase ones.

The `--ignore-case` option makes `sort` treat uppercase and lowercase letters as equals and fixes the problem with MacLeod and Mack:

```
$ sort --ignore-case --key=2 list
Toni Barnett         95020
Jack Cooper          94072
Janet Dempsey        94111
Richard MacDonald    95510
```
David Mack           94114
Alice MacLeod        94114
Tom Winstrom         94201

The next example attempts to sort list on the third field, the ZIP code. In this case sort does not put the numbers in order but rather puts the shortest name first in the sorted list and the longest name last. The \texttt{--key=3} argument instructs sort to begin its comparison with the third field, the ZIP code. A field starts with a blank and includes subsequent blanks. In the case of the list file, the blanks are SPACES. The ASCII value of a SPACE character is less than that of any other printable character, so sort puts the ZIP code that is preceded by the most SPACES first and the ZIP code that is preceded by the fewest SPACES last.

$ sort --key=3 list

David Mack           94114
Jack Cooper          94072
Tom Winstrom         94201
Toni Barnett         95020
Janet Dempsey        94111
Alice MacLeod        94114
Richard MacDonald    95510

The \texttt{-b (ignore-leading-blanks)} option causes sort to ignore leading SPACES within a field. With this option, the ZIP codes come out in the proper order. When sort determines that MacLeod and Mack have the same ZIP codes, it compares the entire lines, putting Alice MacLeod before David Mack (because A comes before D).

$ sort -b --key=3 list

Jack Cooper          94072
Janet Dempsey        94111
Alice MacLeod        94114
David Mack           94114
Tom Winstrom         94201
Toni Barnett         95020
Richard MacDonald    95510
To sort alphabetically by last name when ZIP codes are the same, `sort` needs to make a second pass that sorts on the last name field. The next example shows how to make this second pass by specifying a second sort field and uses the `f` (ignore-case) option to keep the Mack/MacLeod problem from cropping up again:

```
$ sort -b -f --key=3 --key=2 list
Jack Cooper          94072
Janet Dempsey        94111
David Mack           94114
Alice MacLeod        94114
Tom Winstrom         94201
Toni Barnett         95020
Richard MacDonald    95510
```

The next example shows a `sort` command that skips not only fields but also characters. The `k 3.4` option (equivalent to `key=3.4`) causes `sort` to start its comparison with the fourth character of the third field. Because the command does not define an end to the sort field, it defaults to the end of the line. The sort field is the last two digits in the ZIP code.

```
$ sort -fb -k 3.4 list
Tom Winstrom         94201
Richard MacDonald    95510
Janet Dempsey        94111
Alice MacLeod        94114
David Mack           94114
Toni Barnett         95020
Jack Cooper          94072
```

The problem of how to sort by last name within the last two digits of the ZIP code is solved by a second pass covering the last-name field. The `f` option following the `k 2` affects the second pass, which orders by last name only.

```
$ sort -b -k 3.4 -k 2f list
```

The next set of examples uses the `cars` data file. From left to right the columns in the file contain each car's make, model, year of manufacture, mileage, and price:

```
$ cat cars
plym    fury    1970    73      2500
chevy   malibu  1999    60      3000
ford    mustang 1965    45      10000
volvo   s80     1998    102     9850
ford    thundbd 2003    15      10500
chevy   malibu  2000    50      3500
bmw     325i    1985    115     450
honda   accord  2001    30      6000
ford    taurus  2004    10      17000
toyota  rav4    2002    180     750
chevy   impala  1985    85      1550
ford    explor  2003    25      9500
```

Without any options `sort` displays a sorted copy of the file:

```
$ sort cars
bmw     325i    1985    115     450
chevy   impala  1985    85      1550
```

<td>9850</td>
</tr>
</tbody>
</table>

The objective of the next example is to sort by manufacturer and by price within manufacturer. Unless you specify otherwise, a sort field extends to the end of the line. The `\texttt{-k 1}` sort field specifier sorts from the beginning of the line. The command line instructs `sort` to sort on the entire line and then make a second pass, sorting on the fifth field all lines whose first-pass sort fields were the same (`\texttt{-k 5}`):

```bash
$ sort -k 1 -k 5 cars

bmw 325i 1985 115 450
chevy impala 1985 85 1550
chevy malibu 1999 60 3000
chevy malibu 2000 50 3500
ford explor 2003 25 9500
ford mustang 1965 45 10000
ford taurus 2004 10 17000
ford thundbd 2003 15 10500
honda accord 2001 30 6000
plym fury 1970 73 2500
toyota rav4 2002 180 750
volvo s80 1998 102 9850
```
Because no two lines are the same, `sort` makes only one pass, sorting on each entire line. (If two lines differed only in the fifth field, they would be sorted properly on the first pass anyway, so the second pass would be unnecessary.) Look at the lines containing `taurus` and `thundbd`. They are sorted by the second field rather than the fifth, demonstrating that `sort` never made a second pass and so never sorted on the fifth field.

The next example forces the first-pass sort to stop at the end of the first field. The `\( k\ 1,1 \)` option specifies a `start` pointer of the first character of the first field and a `stop` pointer of the last character of the first field. When you do not specify a character within a `start` pointer, it defaults to the first character; when you do not specify a character within a `stop` pointer, it defaults to the last character. Now the `taurus` and `thundbd` are properly sorted by price. But look at the `explor`: It is less expensive than the other Fords, but `sort` has it positioned as the most expensive. The `sort` utility put the list in ASCII collating sequence order, not in numeric order: Thus 9500 comes after 10000 because 9 comes after 1.

```
$ sort -k 1,1 -k 5 cars
bmw     325i    1985    115     450
chevy   impala  1985    85      1550
chevy   malibu  1999    60      3000
chevy   malibu  2000    50      3500
ford    mustang 1965    45      10000
ford    thundbd 2003    15      10500
ford    taurus  2004    10      17000
ford    explor  2003    25      9500
honda   accord  2001    30      6000
plym    fury    1970    73      2500
toyota  rav4    2002    180     750
volvo   s80     1998    102     9850
```

The `\( n\)` (numeric) option on the second pass puts the list in the proper order:

```
$ sort -k 1,1 -k 5n cars
bmw     325i    1985    115     450
chevy   impala  1985    85      1550
chevy   malibu  1999    60      3000
chevy   malibu  2000    50      3500
```
<table>
<thead>

<td>102</td>
<td>9850</td>
</tr>
</tbody>
</table>

The next example again demonstrates that, unless you instruct it otherwise, `sort` orders a file starting with the field you specify and continuing to the end of the line. It does not make a second pass unless two of the first sort fields are the same. Because there is no `stop` pointer on the first sort field specifier, the sort field for the first pass includes the third field through the end of the line. Although this example sorts the cars by years, it does not sort the cars by model within manufacturer within years (Ford Thunderbird comes before Ford Explorer, these lines should be reversed).

```
$ sort -k 3 -k 1 cars
ford      mustang   1965  45   10000
plym      fury       1970  73   2500
bmw       325i       1985  115  450
chevy     impala     1985  85   1550
volvo     s80       1998  102  9850
chevy     malibu    1999  60   3000
chevy     malibu    2000  50   3500
honda     accord     2001  30   6000
toyota    rav4      2002  180  750
ford       thundbd  2003  15   10500
ford       explor   2003  25   9500
ford       taurus   2004  10   17000
```

Specifying an end to the sort field for the first pass allows `sort` to perform its secondary sort properly:
$ sort -k 3,3 -k 1 cars

ford    mustang 1965    45      10000
plym    fury    1970    73      2500
bmw     325i    1985    115     450
chevy   impala 1985    85      1550
volvo   s80     1998    102     9850
chevy   malibu 1999    60      3000
chevy   malibu 2000    50      3500
honda   accord 2001    30      6000
toyota  rav4    2002    180     750
ford    explor 2003    25      9500
ford    thundbd 2003    15     10500
ford    taurus 2004    10     17000

The next examples demonstrate important sorting techniques: putting a list in alphabetical order, merging uppercase and lowercase entries, and eliminating duplicates. The unsorted list follows:

$ cat short
Pear
Pear
apple
pear
Apple

Following is a plain sort:

$ sort short
Apple
Pear
Pear
apple
pear

The following folded sort is a good start, but it does not eliminate duplicates:

$ sort -f short
Apple
apple
Pear
Pear
pear

The \texttt{u} (unique) option eliminates duplicates but without the \texttt{f} the uppercase entries come first:

$ sort -u short
Apple
Pear
apple
pear

When you attempt to use both \texttt{u} and \texttt{f}, some of the entries get lost:

$ sort -uf short
apple
Pear

Two passes is the answer. Both passes are unique sorts, and the first folds lowercase letters onto uppercase ones:

$ sort -u -k 1f -k 1 short
Apple
apple
split: Divides a file into sections

`split [options] [filename [prefix]]`

The `split` utility breaks its input into 1000-line sections named `xaa, xab, xac`, and so on. The last section may be shorter. Options can change the sizes of the sections and lengths of the names.
Arguments

The **filename** is the pathname of the file that **split** processes. If you do not specify an argument or if you specify a hyphen (\( - \)) instead of the **filename**, **split** reads from standard input. The **prefix** is one or more characters that **split** uses to prefix the names of the files it creates. The default prefix is **x**.

Options

Accepts the common options described on page 587.

- **suffix-length=** *len*

  - **a** *len*
    
    Specifies that the filename suffix is *len* characters long (the default is 2).

- **bytes=** *n[u]  b n[u]*

  Breaks the input into files that are *n* bytes long. The *u* is an optional unit of measure that can be *b* (512-byte blocks), *k* (kilobyte or 1,024-byte blocks), or *m* (megabyte or 1,048,576-byte blocks). If you include the unit of measure, **split** counts by this unit in place of bytes.

- **numeric-suffixes**

  - **d**
    
    Specifies numeric suffixes instead of alphabetic suffixes.

- **lines=** *num  l num*

  Breaks the input into files that are *num* lines long (the default is 1,000).

Discussion

By default **split** names the first file it creates **xaa**. The **x** is the default prefix. You can change the prefix with the **prefix** argument on the command line. You can change the number of characters in each filename following the prefix with the **suffix-length** option.

Examples

By default **split** breaks a file into 1,000-line sections with the names **xa a, xab, xac**, and so on. The **wc** utility with the **l** option shows the number of lines in each file. The last file, **xar**, is smaller than the rest.

```bash
$ split /etc/termcap
$ wc -l *

1000  xaa
1000  xab
1000  xac
```
The next example uses the `prefix` argument to specify a filename prefix of `SEC` and uses `--suffix-length` to change the number of letters in the filename suffix to 3:

```
$ split --suffix-length=3 /etc/termcap SEC
$ ls
SECaaa SECaac SECaae SECaag SECaai SECaak SECaam SECaao SECaq
SECaab SECaad SECaaf SECaah SECaaj SECaal SECaan SECaap SECaar
```

`ssh`: Securely executes commands on a remote system

```
ssh [option] [user@]host [command-line]
```

The `ssh` utility runs `command-line` on `host` by starting a shell on the remote system or logs you in on `host`. The `ssh` utility, which can replace `rsh` and `rlogin`, provides secure, encrypted communication between two systems on an insecure network.

**Arguments**

The `host` is the system that you want to log in or run a command on. Unless you have one of several kinds of authentication established, `ssh` prompts you for a username and password for the remote system. When `ssh` is able to log in automatically, it logs in as the user running the `ssh` command or as `user` if `user@` appears on the `ssh` command line.

The `command-line` runs on the remote system. Without `command-line`, `ssh` logs you in on the remote system. You must quote special characters in `command-line` if you do not want them expanded by the local shell.

**Options**

- `f` (not foreground) Sends `ssh` to the background after asking for a password and before executing `command-line`. This option is useful when you want to run the `command-line` in the background but must supply a password. Its use implies `in`.
- `l user` (login) Attempts to log in as `user`. This option is equivalent to using `user@` on the command line.
n (null) Redirects standard input to ssh to come from /dev/null. See \f.

p port
  Connects to port port on the remote host.

q (quiet) Suppresses warning and diagnostic messages.

T (tty) Allocates a pseudo-tty to the ssh process on the remote system. Without this option, when you run a
command on a remote system, ssh does not allocate a tty (terminal) to the process. Instead, ssh attaches
standard input and standard output of the remote process to the ssh session—that is, normally, but not always,
what you want. This option forces ssh to allocate a tty on the remote system so that programs that require a tty
will work.

V (verbose) Displays debugging messages about the connection and transfer. This option is useful if things are
not going as expected.

x (X11) Turns off X11 forwarding.

X (X11) Turns on X11 forwarding. You may not need this option; X11 forwarding may be turned on in a
configuration file.

Notes

OpenSSH

Using public-key encryption, OpenSSH provides two levels of authentication: server and client/user. First, the client
(ssh or scp) verifies that it is connected to the correct server and OpenSSH encrypts communication between the
client and server. Second, once a secure, encrypted connection has been established, OpenSSH confirms that the
user is authorized to log in on or copy files from/to the server. Once the system and user have been verified,
OpenSSH allows different services to pass through the connection. These services include interactive shell sessions
(ssh), remote command execution (ssh and scp), X11 client/server connections, and TCP/IP port tunneling.

Message on initial connection to a server

When you connect to an OpenSSH server for the first time, the OpenSSH client prompts you to confirm that you are
connected to the correct system. This checking can help prevent a person-in-the-middle attack.

The authenticity of host 'grape (192.168.0.3)' can't be established.

Are you sure you want to continue connecting (yes/no)? yes

Warning: Permanently added 'grape,192.168.0.3' (RSA) to the list of known
hosts.

Before you respond to the preceding query, verify that you are logging in on the correct system and not an imposter.
If you are not sure, a telephone call to someone who logs in on that system locally can verify that you are on the
intended system. When you answer yes (you must spell it out), the client appends the server's public host key to the
user's ~/.ssh/known_hosts file on the local system, creating the ~/.ssh directory if necessary. So that it can keep
track of which line in known_hosts applies to which server, OpenSSH prepends the name of the server and the
server's IP address to the line. Subsequently, when you use OpenSSH to connect to that server, the client verifies
that it is connected to the correct server by comparing this key to the one supplied by the server.
Examples

In the first example, Alex uses `ssh` to display a list of the files in his home directory on `kudos`:

```
$ ssh kudos ls
alex@kudos's password:
Work
code
graphs
reports
```

Next the output of the previous command is redirected to the file `kudos_ls`. Because the redirection character (`>` is not escaped, it is interpreted by the local shell, and the file `kudos_ls` is created on the local system.

```
$ ssh kudos ls > kudos_ls
alex@kudos's password:
$ cat kudos_ls
Work
code
graphs
reports
```

The next example quotes the entire command that will run on the remote system. As a result, the local shell does not interpret the redirection character (`>`) but rather passes it to the remote shell. The file `kudos.ls` is created on the remote system (`kudos`), as shown by `ls` run on `kudos`:

```
$ ssh kudos "ls > kudos.ls"
alex@kudos's password:
$ ssh kudos ls
alex@kudos's password:
Work
code
The next command does not quote the pipe symbol (\(\mid\)). As a result the pipe is interpreted by the local shell, which sends the output of the remote \texttt{ls} to standard input of \texttt{less} on the local system:

\begin{verbatim}
$ ssh kudos ls | less
\end{verbatim}

Next \texttt{ssh} executes a series of commands, connected with pipes, on a remote system. The commands are enclosed within single quotation marks so that the local shell does not interpret the pipe symbols and all the commands are run on the remote system.

\begin{verbatim}
$ ssh kudos 'ps -ef | grep nmbd | grep -v grep | cut -c10-15 |xargs kill -1'
\end{verbatim}

The output of \texttt{ps} is piped through \texttt{grep}, which passes all lines containing the string \texttt{nmbd} to another invocation of \texttt{grep}. The second \texttt{grep} passes all lines not containing the string \texttt{grep} to \texttt{cut} (page 627). The \texttt{cut} utility extracts the process ID numbers and passes them to \texttt{xargs} (page 821), which kills the listed processes with a HUP signal (\texttt{kill \(\mid\)1}).

In the following example, \texttt{ssh} without \textit{command-line} logs in on the remote system. Here Alex has used \texttt{watson@kudos} to log in on \texttt{kudos} as \texttt{watson}:

\begin{verbatim}
$ ssh watson@kudos
watson@kudos's password:
Last login: Sat Sep 17 06:51:59 from bravo
$ hostname
kudos
$ exit
\end{verbatim}

Alex now decides to change the password for his \texttt{watson} login on \texttt{kudos}.

\begin{verbatim}
$ ssh watson@kudos passwd
watson@kudos's password:
(current) UNIX password: por
\end{verbatim}

Alex stops as soon as he sees \texttt{passwd} (running on \texttt{kudos}) displaying his password: He knows that something is wrong. For the \texttt{passwd} to work, it must run with a tty (terminal) so that it can turn off character echo (\texttt{stty \#echo})
and thus not display passwords as the user enters them. The \( \texttt{-t} \) option solves the problem by associating a pseudo-tty with the process running \texttt{passwd} on the remote system:

$ ssh -t watson@kudos passwd

watson@kudos's password:

Changing password for watson

(current) UNIX password:

New UNIX password:

Retype new UNIX password:

passwd: all authentication tokens updated successfully

Connection to kudos closed.

$

The \( \texttt{-t} \) option is also useful when you are running a program that uses a character-based/pseudographical interface.

The following example uses \texttt{tar} (page 786) to create an archive file of the contents of the working directory hierarchy. The \( \texttt{-f} \) option causes \texttt{tar} to send its output to standard output. A pipe sends the output of \texttt{tar} running on the local system, via \texttt{ssh}, to \texttt{dd} (page 633) running on the remote system.

$ cat buwd

#!/bin/bash

# back up the working directory to the user's
# home directory on the remote system specified
# by \$machine

# remote system:

machine=speedy

dir=$(basename $(pwd))

filename=$$.dir.tar
echo Backing up $(pwd) to your home directory on $machine

tar -cf - . | ssh $machine "dd obs=256k of=$filename"

echo done. Name of file on $machine is $filename

strings: Displays strings of printable characters

strings [options] file-list

The strings utility displays strings of printable characters from object and other nontext files.

Arguments

The file-list is a list of files that strings processes.

Options

- all Processes whole files. Without this option strings processes only the initialized and loaded parts of an object file.
- bytes= min min Displays strings of characters that are at least min characters long (the default is 4).
- print-file-name

  if Precedes each string with the name of the file that the string comes from.

Discussion

The strings utility can help you determine the contents of nontext files. One application for strings is determining the owner of files in a lost+found directory.

Examples

The following example displays the strings of four or more printable characters in the executable file for the man utility. If you did not know what this file was, these strings could help you determine that it was the man executable.

$ strings /usr/bin/man

...  
man: internal error - cannot find message %d  
/unsafe/
my_xsprintf called with %s

Error parsing config file

No manual entry for %s

using %s as pager

%s, version %s

found man directory %s

found manpath map %s --> %s

corresponding catdir is %s

Line too long in config file

section: %s

...

**stty: Displays or sets terminal parameters**

**stty [options] [arguments]**

Without any arguments, `stty` displays certain parameters affecting the operation of the terminal/terminal emulator. For a list of some of these parameters and an explanation of each, see "Arguments." The arguments establish or change parameters.

**Options**

Accepts the common options described on page 587.

- **all a** Reports on all parameters. This option does not accept arguments.

- **file=/dev/device**

  **F /dev/ device**

  Affects *device*. Without this option `stty` affects the device attached to standard input. You can change the characteristics of a device only if you own its device file or if you are Superuser.

  **save g**

  Generates a report of the current settings in a format you can use as arguments to another `stty` command. This option does not accept arguments.

**Arguments**
The arguments to `stty` specify which terminal parameters `stty` is to alter. Turn on each of the parameters that is preceded by an optional hyphen (indicated in the following list as `[]`) by specifying the parameter without the hyphen. Turn it off by using the hyphen. Unless specified otherwise, this section describes the parameters in their on states.

**Special Keys and Characteristics**

**Columns n** Sets the line width to `n` columns.

**ek** Sets the erase and line kill keys to their default values. Many systems use DELETE and CONTROL-U as the defaults.

**erase x** Sets the erase key to `x`. To specify a control character, precede `x` with CONTROL-V (for example, use CONTROL-V CONTROL-H to indicate CONTROL-H) or use the notation `^h`, where `^` is a caret (SHIFT 6 on most keyboards).

**intr x** Sets the interrupt key to `x`. See `erase x` for conventions.

**kill x** Sets the line kill key to `x`. See `erase x` for conventions.

**rows n** Sets the number of screen rows to `n`.

**sane** Sets the terminal parameters to values that are usually acceptable. The `sane` argument is useful when several `stty` parameters have changed, making it difficult to use the terminal to run `stty` to set things right. If `sane` does not appear to work, try entering the following characters:

```
CONTROL-J stty sane CONTROL-J
```

**susp x** Sets the suspend (terminal stop) key to `x`. See `erase x` for conventions.

**werase x** Sets the word erase key to `x`. See `erase x` for conventions.

**Modes of Data Transmission**

```
[[]]cooked  See raw.
[[]]cstopb  ( stop bits ) Selects two stop bits (cstopb specifies one stop bit).
[[]]parodd  ( parity odd ) Selects odd parity (parodd selects even parity).
[[]]raw     The normal state is raw. When the system reads input in its raw form, it does not interpret the following special characters: erase (usually DELETE), line kill (usually CONTROL-U), interrupt execution (CONTROL-C), and EOF (CONTROL-D). In addition, the system does not use parity bits. Reflecting the humor that is typical of Linux's heritage, you can specify [raw] as cooked.
```

**Treatment of Characters**

```
[[]]echo    Echoes characters as they are typed (full-duplex operation). If a terminal is half-duplex and displays two characters for each one it should display, turn the echo parameter off (echo). Use [echo] when the user is entering passwords.
[[]]echoe   ( echo erase ) The normal setting is echoe, which causes the kernel to echo the character sequence BACKSPACE SPACE BACKSPACE when you use the erase key to delete a character. The effect is to move the cursor backward across the line, removing characters as you delete them.
```
echoke (echo kill erase) The normal setting is echoke. When you use the kill character to delete a line while this option is set, all characters back to the prompt are erased on the current line. When this option is negated, pressing the kill key moves the cursor to the beginning of the next line.

echoprt (echo print) The normal setting is echoprt, which causes characters to disappear as you erase them. When you set echoprt, characters that you erase are displayed between a backslash (\) and a slash (/). For example, if you type the word sort and then erase it by pressing BACKSPACE four times, Linux displays sort\tros/ when echoprt is set. Also, if you use the kill character to delete the entire line, having echoprt set causes the entire line to be displayed as if you had BACKSPACEd to the beginning of the line.

lcase For uppercase-only terminals, translates all uppercase characters into lowercase as they are entered (also [L.CASE]).

nl Accepts only a NEWLINE character as a line terminator. With nl in effect, the system accepts a RETURN character from the terminal as a NEWLINE but sends a RETURN followed by a NEWLINE to the terminal in place of a NEWLINE.

tabs Transmits each TAB character to the terminal as a TAB character. When tabs is turned off ([tabs]), the kernel translates each TAB character into the appropriate number of SPACE s and transmits them to the terminal (also [tab3]).

Job Control Parameters

tostop Stops background jobs if they attempt to send output to the terminal ([tostop] allows background jobs to send output to the terminal).

Notes

The name stty is an abbreviation for set teletypewriter, or set tty (page 807), the first terminal that UNIX was run on. Today stty is commonly thought of as set terminal.

The shells retain some control over standard input when you use them interactively. As a consequence a number of the options available with stty appear to have no effect. For example, the command stty [echo appears to have no effect under tcsh:

tcsh $ stty -echo
tcsh $ date
Fri Feb 18 21:21:14 PST 2005

While stty [echo does work when you are using bash interactively, stty [echo does not. However, you can still use these options to affect shell scripts and other utilities.

$ cat testit
#!/bin/bash
stty -echo
echo -n "Enter a value: 
read a
echo
echo "You entered: $a"
estty echo

$ testit
Enter a value:
You entered: 77

In the preceding example, the kernel does not display the user's response to the **Enter a value:** prompt. The value is retained by the `a` variable and is displayed by the `echo "You entered: $a"` statement.

Examples

The first example shows that `stty` without any arguments displays several terminal operation parameters. (Your system may display more or different parameters.) The character following the `erase =` is the erase key. A `^` preceding a character indicates a CONTROL key. In the example the erase key is set to CONTROL-H. If `stty` does not display the erase character, it is set to its default value of DELETE. If you do not see a kill character, it is set to its default of `^U`.

$ stty

speed 38400 baud; line = 0;
erase = ^H;

Next the `ek` argument returns the erase and line kill keys to their default values:

$ stty ek

The next display verifies the change. The `stty` utility does not display either the erase character or the line kill character, indicating that both are set to their default values:

$ stty

speed 38400 baud; line = 0;
The next example sets the erase key to CONTROL-H. The CONTROL-V quotes the CONTROL-H so that the shell does not interpret it and it is passed to `stty`:

```
$ stty erase CONTROLV CONTROLH
```

```
$ stty
```

```
speed 38400 baud; line = 0;
erase = ^H;
```

Next `stty` sets the line kill key to CONTROL-X. This time the user entered a caret (^) followed by an x to represent CONTROL-X. You can use either a lowercase or uppercase letter.

```
$ stty kill ^X
```

```
$ stty
```

```
speed 38400 baud; line = 0;
erase = ^H; kill = ^X;
```

Now `stty` changes the interrupt key to CONTROL-C:

```
$ stty intr CONTROLV CONTROLC
```

In the following example, `stty` turns off TABs so that the appropriate number of SPACEs is sent to the terminal in place of a TAB. Use this command if a terminal does not automatically expand TABs.

```
$ stty -tabs
```

If you log in and everything appears on the terminal in uppercase letters, give the following command and then check the CAPS LOCK key. If it is set, turn it off:

```
$ STTY -LCASE
```

Turn on `lcase` if you are using a very old terminal that cannot display lowercase characters.

Although no one usually changes the suspend key from its default of CONTROL-Z, you can. Give the following command to change the suspend key to CONTROL-T:

```
$ stty susp ^T
```

`tail`: Displays the last part (tail) of a file
tail [options] [file-list]

The tail utility displays the last part, or end, of a file.

Arguments

The file-list is a list of pathnames of the files that tail displays. When you specify more than one file, tail displays the filename of each file before displaying the lines of the file. If you do not specify an argument or if you specify a hyphen (\-) instead of a filename, tail reads from standard input.

Options

Accepts the common options described on page 587.

bytes=+[n]u

Counts by bytes (characters) instead of lines. The n is an integer that specifies the number of bytes. Thus the command tail 5 displays the last five bytes of a file. The u is an optional unit of measure that can be b (512-byte blocks), k (kilobyte or 1,024-byte blocks), or m (megabyte or 1,048,576-byte blocks). If you include the unit of measure, tail counts by this unit instead of by bytes.

If you put a plus sign (+) in front of n, tail counts from the start of the file instead of the end. The tail utility still displays to the end of the file, even though it starts counting from the beginning. Thus tail +5 causes tail to display from the fifth character through the end of the file.

follow

After copying the last line of the file, tail enters an endless loop, waiting and copying additional lines from the file if the file grows. If you specify multiple files in file-list with this option, tail includes a new header each time it displays output from a different file so that you know which file is being added to. This option is useful for tracking the progress of a process that is running in the background and sending its output to a file. The tail utility continues to wait indefinitely, so you must use the interrupt key to terminate it. See also the s option.

lines= [+ ]n[u]  [n] [+ ]n[u]

Counts by lines (the default). The n is an integer that specifies the number of lines. The u is an optional unit of measure; see the bytes option for an explanation of its use. Although it is not documented, you can use ± n to specify a number of lines without using this option.

If you put a plus sign (+) in front of n, tail counts from the start of the file instead of the end. The tail utility still displays to the end of the file, even though it starts counting from the beginning. Thus tail +5 causes tail to display from the fifth line through the last line of the file.

quiet

Suppresses header information when you specify multiple files in file-list.

sleep-interval=n
$ s n
When used with \( f \), causes \texttt{tail} to sleep for \( n \) seconds between checks for additional output.

Notes

The \texttt{tail} utility displays the last ten lines of its input by default.

Examples

The examples are based on the \texttt{eleven} file:

$ cat eleven
line one
line two
line three
line four
line five
line six
line seven
line eight
line nine
line ten
line eleven

First \texttt{tail} displays the last ten lines of the \texttt{eleven} file (no options):

$ tail eleven
line two
line three
line four
line five
line six
line seven
line eight
line nine
line ten
line eleven

Next it displays the last three lines (lines 3) of the file:

$ tail --lines 3 eleven
line nine
line ten
line eleven

The following example displays the file starting at line 8 (+8):

$ tail -n +8 eleven
line eight
line nine
line ten
line eleven

The next example displays the last six characters in the file (bytes 6). Only five characters are evident (leven); the sixth is a NEWLINE.

$ tail --bytes 6 eleven
leven

The final example demonstrates the -f option. Here tail tracks the output of a make command, which is being sent to the file accounts.out:

$ make accounts > accounts.out &
$ tail -f accounts.out
cc -c trans.c
cc -c reports.c
...
CONTROL-C
$

In the preceding example, using `tail` with `-f` has the same effect as running `make` in the foreground and letting its output go to the terminal. However, using `tail` offers some advantages. First, the output of `make` is saved in a file. (The output would not be saved if you let it go to the terminal.) Second, if you decide to do something else while `make` is running, you can kill `tail` and the screen will be free for you to use while `make` continues in the background. When you are running a large job, such as compiling a large program, you can use `tail` with the `-f` option to check on its progress periodically.

**tar**: Stores or retrieves files *to* from an archive file

```
tar option [modifiers] [file-list]
```

The `tar` (tape archive) utility creates, adds to, lists, and retrieves files from an archive file.

**Arguments**

The `file-list` is a list of pathnames of the files that `tar` archives or extracts.

**Options**

Use only one of the following options to indicate what type of action you want `tar` to take. You can alter the action of the option by following it with one or more modifiers.

- **create** `-c` Creates an archive. This option stores the files named in `file-list` in a new archive. If the archive already exists, it is destroyed before the new archive is created. If a `file-list` argument is a directory, `tar` recursively copies the files within the directory into the archive. Without the `-f` option, the archive is sent to standard output.

- **compare** `-d` (diff) Compares an archive with the corresponding disk files and reports on the differences.

- **help** Displays a list of options and modifiers, with short descriptions of each.

- **append** `-r` Writes the files named in `file-list` to the end of the archive. This option leaves files that are already in the archive intact, so duplicate copies of files may appear in the archive after `tar` finishes. When `tar` extracts the files, the most recent copy of a file in the archive is the one that ends up on the disk.

- **list** `-t` (table of contents) Without a `file-list`, this option produces a table of contents listing all files in an archive. With a `file-list`, it displays the name of each file in the `file-list` each time it occurs in the archive. You can use this option with the `-v` (verbose) option to display detailed information about each file in an archive.

- **update** `-u` Adds the files from `file-list` if they are not already in the archive or if they have been modified since they were last written to the archive. Because of the additional checking required, `tar` runs more
slowly when you specify this option.

- **extract**  **x**  Extracts **file-list** from the archive and writes it to the disk. Overwrites existing files with the same names. Without a **file-list** this option extracts all files from the archive. If the **file-list** includes a directory, **tar** extracts that directory and all the files below it. The **tar** utility attempts to keep the owner, modification time, and access privileges the same as those of the original file. If **tar** reads the same file more than once, the last version read will appear on the disk when **tar** is finished.

Modifiers

You can specify one or more modifiers following an option. If you use the single-character form of the modifier, a leading hyphen is not required. In general, it is a good practice to use the hyphen unless you combine the modifier with other single-character modifiers.

If a modifier takes an argument, that modifier must be the last one in a group. For example, the arguments are arranged legally in the following **tar** command:

```
$ tar -cb 10 -f /dev/ftape memos
```

Conversely, the following **tar** command generates an error:

```
$ tar -cbf 10 /dev/ftape memos
```

```
tar: f: Invalid blocking factor
Try 'tar --help' for more information.
```

The error occurs because the **b** modifier takes an argument but is not the last modifier in a group.

- **blocking-factor**=*n*

  **b**  **n**
  
  Uses *n* as the blocking factor for creating an archive. Use this option only when **tar** is creating an archive directly to a tape. (When **tar** reads a tape archive, it automatically determines the blocking factor.) The value of *n* is the number of 512-byte blocks to write as a single block on the tape.

- **directory**=*dir*

  **C**  **dir**
  
  Changes the working directory to **dir** before processing.

- **checkpoint**

  Displays periodic messages. This option lets you know **tar** is running without displaying all the **verbose** messages.

- **file**=*filename*

  **f**  **filename**
  
  Uses **filename** as the name of the file (device) to hold the archive. The **filename** can be the name of an ordinary file or a device (such as a tape drive). You can use a hyphen (‘-’) instead of the **filename** to refer to standard input when creating an archive and to standard output when extracting files from an archive. The following two commands are equivalent ways of creating a compressed archive of the files under the **/home** directory on **/dev/st0**:

```
$ tar -czf /dev/st0/home.tar.gz
```

```
$ tar -czf - /dev/st0/home.tar.gz
```

Try 'tar --help' for more information.
$ tar -zcf /dev/st0 /home
$ tar -cf - /home | gzip > /dev/st0

dereference  -h  Archives the files that symbolic links point to, not the links themselves.
exclude= file  Does not process the file named file. If file is a directory, no files or directories within that
directory are processed. The file can be an ambiguous file reference; quote special
characters as needed.

ignore-failed-read

When creating an archive, tar normally quits with a nonzero exit status if any of the files in file-list is
unreadable. This option causes tar to continue processing, skipping unreadable files.
bzip  -j  Uses bzip2 (page 56) to compress/decompress files when creating an archive and extracting files from
an archive.

one-file-system

-l  (lowercase "l") When a directory name appears in file-list while creating an archive, tar recursively processes
the files and directories below the named directory. With this option tar stays in the filesystem that contains the
named directory and does not process directories in other filesystems.

tape-length=n

-L n
Asks for a new tape after writing n *1,024 bytes to the current tape. This feature is useful when you are
building archives that are too big to fit on a single tape.
touch  -m  Sets the modification time of extracted files to the time of extraction. Without this option tar attempts
to maintain the modification time of the original file.

absolute-paths

-P  The default behavior of tar is to force all pathnames to be relative paths by
stripping leading slashes. This option disables this feature, so absolute
pathnames remain as absolute paths.
nspare

-S  Linux allows you to have sparse files—that is, large, mostly empty files—on disk.
The empty sections of sparse files do not take up any disk space. When tar
copies a sparse file out of an archive, it normally expands the file to its full
size. As a result, when you restore a sparse file from a tar backup, the file
takes up its full space and may no longer fit in the same disk space as the
original. This option causes tar to handle sparse files efficiently so that they
do not take up unnecessary space either in the archive or when they are
extracted.

verbose

-v  Lists each file as tar reads or writes it. When combined with the t option, v
causes tar to display a more detailed listing of the files in the archive,
showing their ownership, permissions, size, and other information.

interactive or confirmation  -w  Asks you for confirmation before reading or writing each file. Respond with y
Asks you for confirmation before reading or writing each file. Respond with y if you want tar to take the action. Any other response causes tar not to take the action.

**exclude-from=filename**

Similar to the exclude option except that filename specifies a file that contains a list of files to exclude from processing. Each file listed in filename must appear on a separate line.

**gzip or gunzip**

Z Causes tar to use gzip to compress an archive while it is being created and to decompress an archive when extracting files from it. This option also works to extract files from archives that have been compressed with the compress utility.

**compress or uncompress**

Z Uses compress when creating an archive and uncompress when extracting files from an archive.

**Notes**

The help option displays all the tar options and modifiers. The info page on tar provides extensive information, including a tutorial.

You can use ambiguous file references in file-list when you create an archive but not when you extract files from an archive.

The name of a directory file within the file-list references all files and subdirectories within that directory.

The file that tar sends its output to by default is compilation specific; typically it goes to standard output. Use the f option to specify a different filename or device to hold the archive.

When you create an archive using a simple filename in file-list, the file appears in the working directory when you extract it. If you use a relative pathname when you create an archive, the file appears with that relative pathname, starting from the working directory when you extract it. If you use the P option and an absolute pathname when you create an archive, tar extracts the file with the same pathname.

**Examples**

The following example makes a copy of the /home/alex directory hierarchy on a floppy tape device. The v modifier causes the command to list the files it writes to the tape. This command erases anything that was already on the tape. The message from tar explains that the default action is to store all pathnames as relative paths instead of absolute paths, thereby allowing you to extract the files into a different directory on the disk.

```bash
$ tar -cvf /dev/ftape /home/alex

tar: Removing leading '/' from member names.

home/alex/

home/alex/.bash_history
```
In the next example, the same directory is saved on the tape device `/dev/st0` with a blocking factor of 100. Without the `v` modifier, `tar` does not display the list of files it is writing to the tape. The command runs in the background and displays any messages after the shell issues a new prompt.

```
$ tar -cb 100 -f /dev/st0 /home/alex &
[1] 4298
$ tar: Removing leading '/' from member names.
```

The next command displays the table of contents of the archive on tape device `/dev/ftape`:

```
$ tar -tvf /dev/ftape
```

```
  drwxrwxrwx alex/group        0 Jun 30 21:39 2004 home/alex/
  -rw-r--r-- alex/group      678 Aug  6 14:12 2005 home/alex/.bash_history
  -rw-r--r-- alex/group      571 Aug  6 14:06 2005 home/alex/.bash_profile
  drwx------ alex/group        0 Nov  6 22:34 2005 home/alex/mail/
  -rw-------- alex/group     2799 Nov  6 22:34 2005 home/alex/mail/sent-mail
  ...
```

In the last example, Alex creates a gzipped tar archive in `/tmp/alex.tgz`. This approach is a popular way to bundle files that you want to transfer over a network or otherwise share with others. Ending a filename with `.tgz` is one convention for identifying gzipped tar archives. Another convention is to end the filename with `.tar.z`.

```
$ tar -czf /tmp/alex.tgz literature
```

The next command lists the files in the compressed archive `alex.tgz`:

```
$ tar -tzvf /tmp/alex.tgz
```

```
  ...
```

*tee:* Copies standard input to standard output and one or more files
tee [options] file-list

The **tee** utility copies standard input to standard output and to one or more files.

**Arguments**

The **file-list** is a list of the pathnames of files that receive output from **tee**.

**Options**

Without any options, **tee** overwrites the output files if they exist and responds to interrupts. If a file in **file-list** does not exist, **tee** creates it.

- **append**  
  Appends output to existing files rather than overwriting them.

- **ignore-interrupts**
  
  c Causes **tee** not to respond to interrupts.

**Examples**

In the following example, a pipe sends the output from **make** to **tee**, which copies it to standard output and the file **accounts.out**. The copy that goes to standard output appears on the screen. The **cat** utility displays the copy that was sent to the file:

```
$ make accounts | tee accounts.out
    cc -c trans.c
    cc -c reports.c
...
$ cat accounts.out
    cc -c trans.c
    cc -c reports.c
...
```

Refer to page 787 for a similar example that uses **tail** rather than **tee**.

telnet: Connects to a remote system over a network
telnet [options] [remote-system]

The telnet utility implements the TELNET protocol to connect to a remote system over a network.

security: telnet is not secure

The telnet utility is not secure. It sends your username and password over the network as cleartext, which is not a secure practice. Use ssh (page 773) when it is available.

Arguments

The remote-system is the name or IP address of the remote system that telnet connects to. When you do not specify a remote-system, telnet works interactively and prompts you to enter one of the commands described in this section.

Options

\(e\ c\)
   (escape) Changes the escape character from CONTROL-\] to the character c.
\(K\)
   Prevents automatic login.
\(l\ \)username
   Attempts an automatic login on the remote system using username. If the remote system understands how to handle automatic login with telnet, you are prompted for a password.

Discussion

After telnet connects to a remote system, you can put telnet in command mode by typing the escape character (usually CONTROL-[). A remote system should report the escape character it recognizes. To leave command mode, type RETURN on a line by itself.

In command mode telnet displays the telnet> prompt. You can use the following commands in command mode:

?       (help) Displays a list of commands recognized by the telnet utility on the local system.
close   Closes the connection to the remote system. If you specified the name of a system on the command line when you started telnet, close has the same effect as quit: The telnet program quits, and the shell displays a prompt. If you used the open command instead of specifying a remote system on the command line, close returns telnet to command mode.
logout  Logs you off of the remote system; similar to close.

open remote-computer

If you did not specify a remote system on the command line or if the attempt to connect to the system failed, you can specify the name of a remote system interactively with the open command.

quit    Quits the telnet session.
\(z\)
   Suspends the telnet session. When you suspend a session, you return to the login shell on the local system. To resume the suspended telnet session, type \(fg\) at a shell prompt.
Many computers, including non-Linux systems, support the TELNET protocol. The `telnet` utility is a user interface to this protocol for Linux systems that allows you to connect to many different types of systems. Although you typically use `telnet` to log in, the remote computer may offer other services through `telnet`, such as access to special databases.

### Examples

In the following example, the user connects to the remote system named `bravo`. After running a few commands, the user escapes to command mode and uses the `z` command to suspend the `telnet` session so as to run a few commands on the local system. The user gives an `fg` command to the shell to resume using `telnet`. The `logout` command on the remote system ends the `telnet` session, and the local shell displays a prompt.

```
kudos% telnet bravo
Trying 192.168.0.55 ...  
Connected to bravo.
Escape character is '^['.

Fedora Core Release 2 (Tettnang)
Kernel 2.6.5-1.358 on an i686

telnet> z

[1]+ Stopped  telnet bravo
kudos $
...```
kudos $fg
telnet bravo

bravo$ logout
Connection closed by foreign host.
kudos $

test: Evaluates an expression

test expression  
[ expression ]

The test utility evaluates an expression and returns a condition code indicating that the expression is either true (0) or false (not 0). You can place brackets ([ ]) around the expression instead of using the word test (second format).

Arguments

The expression contains one or more criteria (see the following list) that test evaluates. A \texttt{\&} separating two criteria is a Boolean AND operator: Both criteria must be true for test to return a condition code of true. A \texttt{|} is a Boolean OR operator. When \texttt{|} separates two criteria, one or the other (or both) of the criteria must be true for test to return a condition code of true.

You can negate any criterion by preceding it with an exclamation point (!). You can group criteria with parentheses. If there are no parentheses, \texttt{\&} takes precedence over \texttt{|}, and test evaluates operators of equal precedence from left to right.

Within the expression you must quote special characters, such as parentheses, so that the shell does not interpret them but rather passes them to test.

Because each element, such as a criterion, string, or variable within the expression, is a separate argument, you must separate each element from other elements with a SPACE. Table V-25 lists the criteria you can use within the expression. Table V-26 lists test's relational operators.

<table>
<thead>
<tr>
<th>Table V-25. Criteria</th>
<th>Criterion</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>True if string is not a null string.</td>
<td></td>
</tr>
<tr>
<td>\texttt{\textless} string \texttt{\textgreater}</td>
<td>True if string has a length greater than zero.</td>
<td></td>
</tr>
<tr>
<td>\texttt{\textbar} string \texttt{\textbar}</td>
<td>True if string has a length of zero.</td>
<td></td>
</tr>
<tr>
<td>string1 = string2</td>
<td>True if string1 is equal to string2.</td>
<td></td>
</tr>
<tr>
<td>string1 != string2</td>
<td>True if string1 is not equal to string2.</td>
<td></td>
</tr>
</tbody>
</table>
Criterion | Meaning
--- | ---
\text{int1 relop int2} | True if integer \text{int1} has the specified algebraic relationship to integer \text{int2}. The relop is a relational operator from Table V-26. As a special case, \text{\l string}, which gives the length of \text{string}, may be used for \text{int1} or \text{int2}.

\text{file1 ef file2} | True if \text{file1} and \text{file2} have the same device and inode numbers.
\text{file1 nt file2} | True if \text{file1} was modified after \text{file2} (the modification time of \text{file1} is newer than that of \text{file2}).
\text{file1 ot file2} | True if \text{file1} was modified before \text{file2} (the modification time of \text{file1} is older than that of \text{file2}).
\text{b filename} | True if the file named \text{filename} exists and is a block special file.
\text{c filename} | True if the file named \text{filename} exists and is a character special file.
\text{d filename} | True if the file named \text{filename} exists and is a directory.
\text{e filename} | True if the file named \text{filename} exists.
\text{f filename} | True if the file named \text{filename} exists and is an ordinary file.
\text{g filename} | True if the file named \text{filename} exists and its setgid bit (page 94) is set.
\text{G filename} | True if the file named \text{filename} exists and is associated with the group that is the primary group of the user running the command (same effective group ID).
\text{k filename} | True if the file named \text{filename} exists and its sticky bit (page 903) is set.
\text{L filename} | True if the file named \text{filename} exists and is a symbolic link.
\text{O filename} | True if the file named \text{filename} exists and is owned by the user running the command (same effective user ID).
\text{p filename} | True if the file named \text{filename} exists and is a named pipe.
\text{r filename} | True if the file named \text{filename} exists and you have read permission for it.
\text{s filename} | True if the file named \text{filename} exists and contains information (has a size greater than 0 bytes).
\text{t file-descriptor} | True if \text{file-descriptor} is associated with the screen/keyboard. The \text{file-descriptor} for standard input is 0, for standard output is 1, and for standard error is 2.
\text{u filename} | True if the file named \text{filename} exists and its setuid (page 94) is set.
\text{w filename} | True if the file named \text{filename} exists and you have write permission for it.
\text{x filename} | True if the file named \text{filename} exists and you have execute permission for it.

| Table V-26. Relational operators |
|---|---|
| Relop | Meaning |
| \text{eq} | Equal to |
| \text{ge} | Greater than or equal to |
| \text{gt} | Greater than |
| \text{le} | Less than or equal to |
| \text{lt} | Less than |
| \text{ne} | Not equal to |

Notes

The \text{test} command is built into the Bourne Again and TC Shells.

Examples

The following examples demonstrate the use of the \text{test} utility in Bourne Again Shell scripts. Although \text{test}
works from a command line, it is more commonly employed in shell scripts to test input or verify access to a file.

The first example prompts the user, reads a line of input into a variable, and uses the synonym for `test`, `[]`, to see whether the user entered `yes`:

```bash
$ cat user_in

echo -n "Input yes or no: "
read user_input

if [ "$user_input" = "yes" ]
    then
    echo You input yes.
fi
```

The next example prompts for a filename and then uses the synonym for `test`, `[]`, to see whether the user has read access permission (`r`) for the file and (`a`) whether the file contains information (`s`):

```bash
$ cat validate

echo -n "Enter filename: "
read filename

if [ -r "$filename" -a -s "$filename" ]
    then
    echo File $filename exists and contains information.
    echo You have read access permission to the file.
fi
```

The `t 1` criterion checks whether the process running `test` is sending standard output to the screen. If it is, the `test` utility returns a value of `true` (0). The shell stores the exit status of the last command it ran in the `?` variable. The following script tests whether its output is going to a terminal:

```bash
$ cat term

test -t 1

echo "This program is (=0) or is not (=1) sending its output to a terminal:" $?
```
First `term` is run with the output going to the terminal:

```
$ term
This program is (=0) or is not (=1)
sending its output to a terminal: 0
```

The next example runs `term` and redirects the output to a file. The contents of the file `temp` show that `test` returned 1, indicating that its output was not going to a terminal.

```
$ term > temp
$ cat temp
This program is (=0) or is not (=1)
sending its output to a terminal: 1
```

**top: Dynamically displays process status**

`top [options]`

The `top` utility displays information about the status of the local system including information about current processes.

**Options**

Although `top` does not require the use of hyphens with options, it is a good idea to include them for clarity and consistency with other utilities. You can cause `top` to run as though you had specified any of the options by giving commands to the utility while it is running. See "Discussion" for more information.

- `-d ss.tt`
  - (delay) Specifies `ss.tt` as the number of seconds and tenths of seconds of delay from one display update to the next. The default is 3 seconds.
- `-i`
  - Ignores idle and zombie processes. (A zombie process is one without a parent.)
- `-n n`
  - (number) Specifies the number of iterations: `top` updates the display `n` times and exits.
- `-p n`
  - (PID) Monitors the process with a PID of `n`. You can use this option up to 20 times on a command line or specify `n` as a comma-separated list of up to 20 PID numbers.
- `-s (secure)` Runs `top` in secure mode, restricting commands that you can use while `top` is running to those that pose less security risk.
- `-S (sum)` Causes `top` to run in cumulative mode. In cumulative mode, the CPU times reported for processes
include CPU times accumulated by child processes that are now dead.

Discussion

The first few lines that top displays summarize the status of the local system. You can turn each of these lines on or off with the toggle switches (interactive command keys) specified in the following descriptions. The first line is the same as the output of the uptime utility and shows the current time, the amount of time the local system has been running since it was last booted, the number of users logged in, and the load averages from the last 1, 5, and 15 minutes (toggle l [lowercase "l"]). The second line indicates the number of processes that are currently running (toggle t). The next three lines report on CPU (also toggle t), memory (toggle m), and swap space (also toggle m) use.

The rest of the display reports on individual processes, listed in descending order by current CPU usage (the most CPU-intensive process is listed first). By default top displays the number of processes that fit on the screen.

Table V-27 describes the meanings of the fields displayed for each process.

<table>

</table>

While top is running, you can use the following commands to modify its behavior. Some of these commands are disabled when you run top in secure mode (ls option).

- **h (help)** Displays a summary of the commands you can use while top is running.
- **k (kill)** Allows you to kill a process. Unless you are Superuser, you can kill only processes you own. When you use this command, top prompts you for the PID of the process and the signal to send to the process. You can enter either a signal number or name. (See Table 11-5 on page 494 for a list of signals.) This command is disabled in secure mode.
- **n (number)** When you give this command, top asks you to enter the number of processes you want it to display. If you enter 0 (the default) top shows as many processes as fit on the screen.
- **q (quit)** Terminates top.
- **r (renice)** Changes the priority of a running process (refer to nice on page 734). Unless you are Superuser, you can change the priority of only your own processes and even then only to lower the priority by entering a positive value. Superuser can enter a negative value, increasing the priority of the process. This command is
The `top` utility is similar to `ps` but periodically updates the display, enabling you to watch the behavior of the local system over time.

This utility shows only as much of the command line for each process as fits on a line. If a process is swapped out, `top` replaces the command line with the name of the command in parentheses.

The `top` utility uses the `proc` filesystem: When `proc` is not mounted, `top` does not work.

Requesting continuous updates is almost always a mistake. The display updates too quickly and the system load increases dramatically.

### Examples

The following display is the result of a typical execution of `top`:

```
top - 23:30:31 up 18 days, 30 min, 6 users,  load average: 0.08, 0.07, 0.01
Tasks: 125 total, 1 running, 124 sleeping, 0 stopped, 0 zombie

```
touch: Changes a file's access and/or modification time

touch [options] file-list

The `touch` utility changes the access and/or modification time of a file to the current time or a time you specify.

Arguments

The `file-list` is a list of the pathnames of the files that `touch` will update.

Options

Accepts the common options described on page 587. Without any options `touch` changes the access and modification times to the current time. When you do not specify the `no-create` option, `touch` creates files that do not exist.

- `time=atime or time=access` Updates the access time only, leaving the modification time unchanged.
- `no-create` Does not create files that do not exist.

`date=datestring`

- `d datestring` Updates times with the date specified by `datestring`. Most familiar formats are permitted for `datestring`. Components of the date and time not included in `datestring` are assumed to be the current date and time. This option may not be used with `t`.
- `time=mtime or time=modify` Updates the modification time only, leaving the access time unchanged.
- `reference= file or file` Updates times with the times of `file`.
Changes times to the date specified by the argument. The nn is the number of the month (01–12), dd is the day of the month (01–31), hh is the hour based on a 24-hour clock (00–23), and mm is the minutes (00–59). You must specify at least these fields. You can specify the number of seconds past the start of the minute with .ss.

The optional cc specifies the first two digits of the year (the value of the century minus 1), and yy specifies the last two digits of the year. When you do not specify a year, touch assumes the current year. When you do not specify cc, touch assumes 20 for yy in the range 068 and 19 for yy in the range 6999.

This option may not be used with -d.

Examples

The first three commands show touch updating an existing file. The ls utility with the l option displays the modification time of the file. The last three commands show touch creating a file.

$ ls -l program.c
-rw-r--r-- 1 alex group 5860 Apr 21 09:54 program.c
$ touch program.c
$ ls -l program.c
-rw-r--r-- 1 alex group 5860 Aug 13 19:01 program.c

$ ls -l read.c
ls: read.c: No such file or directory
$ touch read.c
$ ls -l read.c
-rw-rw-r-- 1 alex group 0 Aug 13 19:01 read.c

The next example demonstrates the use of the -a option to change the access time only and the -d option to specify a date for touch to use instead of the current date and time. The first ls command displays the file modification times; the second ls (with the -t time=atime option) displays file access times. In this case the touch command does not have the intended effect: The access times of the files cases and excerpts are changed to 7:00 on the current date and three unwanted files are created. Because the date was not quoted (by surrounding it with double quotation marks), touch assumed that 7:00 went with the -d option and created the pm, Jul, and 30 files.

$ ls -l
The final example is the same as the preceding one but correctly encloses the date within double quotation marks. After the `touch` command is executed, `ls` shows that the access times of the files `cases` and `excerpts` have been updated as expected:

```
$ touch -a -d 7:00 pm Jul 30 cases excerpts

$ ls -l
-rw-rw-r--   1 alex group 0 Aug 11 12:23 30
-rw-rw-r--   1 alex group 0 Aug 11 12:23 Jul
-rw-rw-r--   1 alex group 45 Aug 11 07:00 cases
-rw-rw-r--   1 alex group 14 Aug 11 07:00 excerpts
-rw-rw-r--   1 alex group 0 Aug 11 12:23 pm

$ ls -l --time=atime
-rw-rw-r--   1 alex group 0 Aug 11 07:00 30
-rw-rw-r--   1 alex group 0 Aug 11 07:00 Jul
-rw-rw-r--   1 alex group 45 Aug 11 07:00 cases
-rw-rw-r--   1 alex group 14 Aug 11 07:00 excerpts
-rw-rw-r--   1 alex group 0 Aug 11 07:00 pm
```

```
The final example is the same as the preceding one but correctly encloses the date within double quotation marks. After the `touch` command is executed, `ls` shows that the access times of the files `cases` and `excerpts` have been updated as expected:

```
tr: Replaces specified characters

tr [options] string1 [string2]

The tr utility reads standard input and, for each input character, maps it to an alternate character, deletes the character, or leaves the character alone. This utility reads from standard input and writes to standard output.

Arguments

The tr utility is typically used with two arguments, string1 and string2. The position of each character in the two strings is important: Each time tr finds a character from string1 in its input, it replaces that character with the corresponding character from string2.

With one argument, string1, and the delete option, tr deletes the characters specified in string1. The option squeeze-repeats replaces multiple sequential occurrences of characters in string1 with single occurrences (for example, abc becomes abc).

Ranges

A range of characters is similar in function to a character class within a regular expression (page 829). GNU TR does not support ranges (character classes) enclosed within brackets. You can specify a range of characters by following the character that appears earlier in the collating sequence with a hyphen and then the character that comes later in the collating sequence. For example, 16 expands to 123456. Although the range A-Z expands as you
would expect in ASCII, this approach does not work when you use the EBCDIC collating sequence, as these characters are not sequential in EBCDIC. See "Character Classes" for a solution to this issue.

Character Classes

A TR character class is not the same as described elsewhere in this book. (GNU documentation uses the term list operator for what this book calls a character class.) You specify a character class as '[: class :]', where class is a character class from Table V-28. You must specify a character class in string1 unless you are performing case conversion (see "Examples" later in this section) or are using the -d and -s options together.

Table V-28. Character classes

<table>
<thead>
<tr>
<th>Class</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>alnum</td>
<td>Letters and digits</td>
</tr>
<tr>
<td>alpha</td>
<td>Letters</td>
</tr>
<tr>
<td>blank</td>
<td>Whitespace</td>
</tr>
<tr>
<td>ctrl</td>
<td>CONTROL characters</td>
</tr>
<tr>
<td>digit</td>
<td>Digits</td>
</tr>
<tr>
<td>graph</td>
<td>Printable characters but not SPACEs</td>
</tr>
<tr>
<td>lower</td>
<td>Lowercase letters</td>
</tr>
<tr>
<td>print</td>
<td>Printable characters including SPACEs</td>
</tr>
<tr>

</tr>
<tr>
<td>space</td>
<td>Horizontal or vertical whitespace</td>
</tr>
<tr>
<td>upper</td>
<td>Uppercase letters</td>
</tr>
<tr>
<td>xdigit</td>
<td>Hexadecimal digits</td>
</tr>
</tbody>
</table>

Options

- complement [c] Complements string1, causing TR to match all characters except those in string1.
- delete [d] Deletes characters that match those specified in string1. If you use this option with the squeeze-repeats option, you must specify both string1 and string2 (see "Notes").
- help Summarizes how to use TR, including the special symbols you can use in string1 and string2.
- squeeze-repeats
  - [s] Replaces multiple sequential occurrences of a character in string1 with a single occurrence of the character when you call TR with only one string argument. If you use both string1 and string2, the tr utility first translates the characters in string1 to those in string2 and then reduces multiple sequential occurrences of characters in string2.
- truncate-set1 [t] Truncates string1 so it is the same length as string2 before processing input.

Notes

When string1 is longer than string2, the initial portion of string1 (equal in length to string2) is used in the
When \texttt{string1} is longer than \texttt{string2}, \texttt{tr} uses the last character of \texttt{string1} to extend \texttt{string1} to the length of \texttt{string2}. In this case \texttt{tr} departs from the POSIX standard, which does not define a result.

If you use the \texttt{-delete} and \texttt{squeeze-repeats} options at the same time, \texttt{tr} deletes the characters in \texttt{string1} and then reduces multiple sequential occurrences of characters in \texttt{string2}.

Examples

You can use a hyphen to represent a range of characters in \texttt{string1} or \texttt{string2}. The two command lines in the following example produce the same result:

\begin{verbatim}
$ echo abcdef | tr  'abcdef' 'xyzabc'
exyabc
$ echo abcdef | tr  'a-f' 'x-za-c'
exyabc
\end{verbatim}

The next example demonstrates a popular method for disguising text, often called ROT13 (rotate 13) because it replaces the first letter of the alphabet with the thirteenth, the second with the fourteenth, and so forth.

\begin{verbatim}
$ echo The punchline of the joke is ... | > tr 'A-M N-Z a-m n-z' 'N-Z A-M n-z a-m'
Gur chapuyvar bs gur wbxr vf ... 
\end{verbatim}

To make the text intelligible again, reverse the order of the arguments to \texttt{tr}:

\begin{verbatim}
$ echo Gur chapuyvar bs gur wbxr vf ... | > tr 'N-Z A-M n-z a-m' 'A-M N-Z a-m n-z'
The punchline of the joke is ...
\end{verbatim}

The \texttt{-delete} option causes \texttt{tr} to delete selected characters:

\begin{verbatim}
$ echo If you can read this, you can spot the missing vowels! | > tr --delete 'aeiou'
If y cn rd ths, y cn spt th mssng vwls!
\end{verbatim}

In the following example, \texttt{TR} replaces characters and reduces pairs of identical characters to single characters:
$ echo tennessee | tr -s 'tnse' 'srne'
serene

The next example replaces each sequence of nonalphabetic characters (the complement of all the alphabetic characters as specified by the character class alpha) in the file draft1 with a single NEWLINE character. The output is a list of words, one per line.

$ tr --complement --squeeze-repeats '[:alpha:]' '\n' < draft1

The next example uses character classes to upshift the string hi there:

$ echo hi there | tr '[:lower:]' '[:upper:]'
HI THERE

tty: Displays the terminal pathname

tty [option]

The tty utility displays the pathname of standard input if it is a terminal and displays not a tty if it is not a terminal. The exit status is 0 if standard input is a terminal and 1 if it is not.

Arguments

There are no arguments.

Options

Accepts the common options described on page 587.

silent or quiet s Causes tty not to print anything. The exit status of tty is set.

Notes

The term tty is short for teletypewriter, the terminal device on which UNIX was first run. This command appears in UNIX, and Linux has kept it for the sake of consistency and tradition.

Examples

The following example illustrates the use of tty:
$ tty
/dev/pts/11
$ echo $?
0
$ tty < memo
not a tty
$ echo $? 
1

tune2fs: Changes parameters on an ext2 or ext3 filesystem

```
tune2fs [options] device
```

The `tune2fs` utility displays and modifies filesystem parameters on `ext2` filesystems and on `ext3` filesystems, which are modified `ext2` filesystems. This utility can also set up journaling on an `ext2` filesystem, turning it into an `ext3` filesystem. With typical filesystem permissions, `tune2fs` must be run as `root`.

**Arguments**

The `device` is the name of the device, such as `/dev/hda8`, that holds the filesystem whose parameters you want to display or modify.

**Options**

- `c n`
  
  `(count)` Sets the maximum number of times the filesystem can be mounted between filesystem checks to `n`. Set `n` to `0` (zero) to disregard this parameter.

- `C n`
  
  `(count)` Sets the number of times the filesystem has been mounted without being checked to `n`. This option is useful for staggering filesystem checks (see "Discussion") and for forcing a check the next time the system boots.

- `e behavior`
  
  `(error)` Specifies what the kernel will do when it detects an error. Set `behavior` to `continue` (continues execution), `remount-ro` (remounts the filesystem readonly), or `panic` (causes a kernel panic). Regardless of how you set this option, an error will cause `fsck` to check the filesystem next time the system boots.

- `i n [u]`
  
  `(interval)` Sets the maximum time between filesystem checks to `n` time periods. Without `u` or with `u` set to `d`, the time period is days. Set `u` to `w` to set the time period to weeks; `m` for months. Set `n` to `0` (zero) to disregard this parameter. Because a filesystem check is forced only when the system is booted the time specified by this option may be exceeded.
**j** (journal) Adds an **ext3** journal to an **ext2** filesystem. For more information refer to "journaling filesystem" on page 883.

**l** (list) Lists information about the filesystem.

**T** date

Sets the time the filesystem was last checked to date. The date is the time and date in the format `yyymmdd [ hh [ mm ] ss ]`. Here `mm` is the number of the month (01–12) and `dd` is the day of the month (01–31). You must specify at least these fields. The `hh` is the hour based on a 24-hour clock (00–23), `mm` is the minutes (00–59), and `.ss` is the number of seconds past the start of the minute. You can also specify date as `now`.

**Discussion**

Checking a large filesystem can take a long time. Use the `C` and/or `T` options to stagger filesystem checks so they do not all happen at the same time. When all the filesystem checks occur at the same time it can take a long time for the system to boot.

**Examples**

Following is the output of `tune2fs` run with the **l** option on a typical **ext3** filesystem:

```
# /sbin/tune2fs -l /dev/hda2

tune2fs 1.35 (28-Feb-2004)

Filesystem volume name:   /p04

</tbody>
</table>
umask: Establishes the file-creation permissions mask

**umask [mask]**

The `umask` builtin specifies a mask that the system uses to set access permissions when you create a file. This builtin works slightly differently in each of the shells.

**Arguments**

The `mask` can be a three-digit octal number (`bash` and `tcsh`) or a symbolic value (`bash`) such as you would use with `chmod` (page 604). The `mask` specifies the permissions that are *not* allowed.

When `mask` is an octal number, the digits correspond to the permissions for the owner of the file, members of the group the file is associated with, and everyone else. Because the `mask` specifies the permissions that are *not* allowed, the system subtracts each of these digits from 7 when you create a file. The resulting three octal numbers specify the access permissions for the file (the numbers you would use with `chmod`). A `mask` that you give as a symbolic value also specifies the permissions that are *not* allowed. See "Notes."

Without any arguments, `umask` displays the file-creation permissions `mask`.

**Notes**

Most utilities and applications do not attempt to create files with execute permissions, regardless of the value of `mask`; they assume that you do not want an executable file. As a result, when a utility or application such as `touch` creates a file, the system subtracts each of the digits in `mask` from 6. An exception occurs with `mkdir`, which does assume that you want the execute (access in the case of a directory) bit set. See "Examples."

The `umask` program is a builtin in `bash` and `tcsh` and generally goes in the initialization file for your shell (`~/.bash_profile [bash] or ~/.login [tcsh]`).

Under `bash` the argument `g=r,o=r` turns on the write bit in the `mask` for groups and other users (the mask is 0033), causing those bits to be off in file permissions (744 or 644). Refer to `chmod` on page 604 for more information about symbolic permissions.

**Examples**

The following commands set the file-creation permissions mask and display the mask and its effect when you create a file and a directory. The mask of 022, when subtracted from 777, gives permissions of 644 (`rw-r--r--`) for a file and 755 (`rwxr-xr-x`) for a directory:

```
$ umask 022
$ umask
022
$ touch afile
```
$ mkdir adirectory

$ ls -ld afile adirectory
drwxr-xr-x  2 max max 4096 Jul 24 11:25 adirectory
-rw-r--r--  1 max max 0 Jul 24 11:25 afile

The next example sets the same mask value symbolically:

$ umask g=rx,o=rx

$ umask

022

uniq: Displays unique lines

uniq [options] [input-file] [output-file]

The uniq utility displays its input, removing all but one copy of successive repeated lines. If the file has been sorted (see sort on page 762), uniq ensures that no two lines that it displays are the same.

Arguments

When you do not specify the input-file, uniq reads from standard input. When you do not specify the output-file, uniq writes to standard output.

Options

Accepts the common options described on page 587. A field is a sequence of characters bounded by SPACE s, TABs, NEWLINEs, or a combination of these characters.

**count**  
\( \texttt{c} \) Precedes each line with the number of occurrences of the line in the input file.

**repeated**  
\( \texttt{d} \) Displays one copy of lines that are repeated; does not display lines that are not repeated.

**skip-fields=**  
\( \texttt{nfield} \) Ignores the first nfield blank-separated fields of each line. The uniq utility bases its comparison on the remainder of the line, including the leading blanks of the next field on the line (see the \( \texttt{skip-chars} \) option).

**ignore-case**  
\( \texttt{i} \) Ignores case when comparing lines.

**skip-chars=**  
\( \texttt{nchar} \)
snchar
Ignores the first nchar characters of each line. If you also use the skip-fields option, uniq ignores the first nfield fields followed by nchar characters. You can use this option to skip over leading blanks of a field.

unique u
Displays only lines that are not repeated.

check-chars=nchar

w nchar
Compares up to nchars characters on a line after honoring the skip-fields and skip-chars options. By default uniq compares the entire line.

Examples

These examples assume that the file named test in the working directory contains the following text:

```
$ cat test
boy took bat home
boy took bat home
girl took bat home
dog brought hat home
dog brought hat home
dog brought hat home
```

Without any options, uniq displays only one copy of successive repeated lines:

```
$ uniq test
boy took bat home
girl took bat home
dog brought hat home
```

The --count option displays the number of consecutive occurrences of each line in the file:

```
$ uniq --count test
   2 boy took bat home
```
1 girl took bat home
3 dog brought hat home

The `repeated` option displays only lines that are consecutively repeated in the file.

$ uniq --repeated test

boy took bat home
dog brought hat home

The `unique` option displays only lines that are not consecutively repeated in the file:

$ uniq --unique test

girl took bat home

Next the `skip-fields` option skips the first field in each line, causing the lines that begin with `boy` and the one that begins with `girl` to appear to be consecutive repeated lines. The `uniq` utility displays only one occurrence of these lines:

$ uniq --skip-fields=1 test

boy took bat home
dog brought hat home

The next example uses both the `f` (`skip-fields`) and `s` (`skip-chars`) arguments first to skip two fields and then to skip two characters. The two characters this command skips include the SPACE that separates the second and third fields and the first character of the third field. Ignoring these characters, all the lines appear to be consecutive repeated lines containing the string `at home`. The `uniq` utility displays only the first of these lines:

$ uniq -f 2 -s 2 test

boy took bat home

w: Displays information about system users

w [options] [username]

The `w` utility displays the names of users who are currently logged in, together with their terminal device numbers, the times they logged in, the commands they are running, and other information.
Options

`f` (from) Removes the FROM column. For users who are directly connected, this field contains a hyphen.
`h` (no header) Suppresses the header line.
`s` (short) Displays less information: username, terminal device, idle time, and command.

Arguments

The `username` restricts the display to information about that user.

Discussion

The first line that `w` displays is the same as that displayed by `uptime`. This line includes the time of day, how long the system has been running (in days, hours, and minutes), how many users are logged in, and how busy the system is (load average). From left to right, the load averages indicate the number of processes that have been waiting to run in the past 1 minute, 5 minutes, and 15 minutes.

The columns of information that `w` displays have the following headings:

```
USER TTY FROM LOGIN@ IDLE JCPU PCPU WHAT
```

The `USER` is the username of the user. The `TTY` is the device name for the line that the user is on. The `FROM` is the system name that a remote user is logged in from; it is a hyphen for a local user. The `LOGIN@` gives the date and time the user logged in. The `IDLE` indicates how many minutes have elapsed since the user last used the keyboard. The `JCPU` is the CPU time used by all processes attached to the user's tty, not including completed background jobs. The `PCPU` is the time used by the process named in the `WHAT` column. The `WHAT` is the command that user is running.

Examples

The first example shows the full list produced by the `w` utility:

```
$ w
10:26am  up 1 day, 55 min,  6 users,  load average: 0.15, 0.03, 0.01
USER     TTY      FROM              LOGIN@   IDLE   JCPU   PCPU  WHAT
alex     tty1     -                Fri 9am 20:39m  0.22s  0.01s  vim td
alex     tty2     -                Fri 5pm 17:16m  0.07s  0.07s  -bash
root     pts/1    -                Fri 4pm 14:28m  0.20s  0.07s  -bash
jenny    pts/2    -                Fri 5pm  3:23   0.08s  0.08s  /bin/bash
```
The next example shows the `-s` option producing an abbreviated listing:

$$w -s$$

10:30am up 1 day, 58 min, 6 users, load average: 0.15, 0.03, 0.01

<table>
<thead>
<tr>
<th>USER</th>
<th>TTY</th>
<th>FROM</th>
<th>IDLE</th>
<th>WHAT</th>
</tr>
</thead>
<tbody>
<tr>
<td>alex</td>
<td>tty1</td>
<td>-</td>
<td>20:43</td>
<td>vim td</td>
</tr>
<tr>
<td>alex</td>
<td>tty2</td>
<td>-</td>
<td>17:19</td>
<td>-bash</td>
</tr>
<tr>
<td>root</td>
<td>pts/1</td>
<td>-</td>
<td>14:31</td>
<td>-bash</td>
</tr>
<tr>
<td>jenny</td>
<td>pts/2</td>
<td>-</td>
<td>0.20</td>
<td>vim memo.030125</td>
</tr>
<tr>
<td>hls</td>
<td>pts/3</td>
<td>potato</td>
<td>0.00</td>
<td>w -s</td>
</tr>
</tbody>
</table>

The final example requests information only about Alex:

$$w alex$$

10:35am up 1 day, 1:04, 6 users, load average: 0.06, 0.01, 0.00

<table>
<thead>
<tr>
<th>USER</th>
<th>TTY</th>
<th>FROM</th>
<th>LOGIN@</th>
<th>IDLE</th>
<th>JCPU</th>
<th>PCPU</th>
<th>WHAT</th>
</tr>
</thead>
<tbody>
<tr>
<td>alex</td>
<td>tty1</td>
<td>-</td>
<td>Fri 9am</td>
<td>20:48</td>
<td>0.22</td>
<td>0.01</td>
<td>vim td</td>
</tr>
<tr>
<td>alex</td>
<td>tty2</td>
<td>-</td>
<td>Fri 5pm</td>
<td>17:25</td>
<td>0.07</td>
<td>0.07</td>
<td>-bash</td>
</tr>
</tbody>
</table>

**wc**: Displays the number of lines, words, and bytes

**wc [options] [file-list]**

The `wc` utility displays the number of lines, words, and bytes in its input. When you specify more than one file on the command line, `wc` displays totals for each file as well as totals for the group of files.

**Arguments**

The `file-list` is a list of the pathnames of one or more files that `wc` analyzes. When you omit `file-list`, the `wc` utility takes its input from standard input.

**Options**
Accepts the common options described on page 587.

- **bytes** `-c` Displays only the number of bytes in the input.
- **lines** `-l` (lowercase "l") Displays only the number of lines (that is, NEWLINE characters) in the input.

**max-line-length**

- **L** Displays the length of the longest line in the input.
- **chars** `-m` Displays only the number of characters in the input.
- **words** `-w` Displays only the number of words in the input.

**Notes**

A word is a sequence of characters bounded by SPACE s, TAB s, NEWLINE s, or a combination of these characters.

**Examples**

The following command analyzes the file named `memo`. The numbers in the output represent the number of lines, words, and bytes in the file:

```
$ wc memo
  5   31  146 memo
```

The next command displays the number of lines and words in three files. The line at the bottom, with the word **total** in the right column, contains the sum of each column.

```
$ wc -lw memo1 memo2 memo3
  10   62 memo1
  12   74 memo2
  12   68 memo3
  34  204 total
```

**which:** Shows where in PATH a command is located

**which command-list**

For each command in **command-list**, the **which** utility searches the directories in the **PATH** variable (page 284) and displays the absolute pathname of the first file it finds whose simple filename is the same as the command.
Arguments

The *command-list* is a list of one or more commands (utilities) that *which* searches for. For each command *which* searches the directories listed in the *PATH* environment variable, in order, and displays the full pathname of the first command (executable file) it finds. If *which* does not locate a command, it displays a message.

Options

- `all` Displays all matching executable files in *PATH*, not just the first.
- `read-alias` Reads aliases from standard input and reports on matching aliases in addition to executable files in *PATH* (turn off with `skip-alias`).

- `read-functions` Reads shell functions from standard input and reports on matching functions in addition to executable files in *PATH* (turn off with `skip-functions`).
- `show-dot` Displays `/` in place of the absolute pathname when a directory in *PATH* starts with a period and a matching executable file is in that directory (turn off with `skip-dot`).
- `show-tilde` Displays a tilde (`~`) in place of the absolute pathname of the user's home directory where appropriate. This option is ignored when Superuser runs *which*.
- `tty-only` Do not process more options (to the right of this option) if the process running *which* is not attached to a terminal.

Notes

Many distributions define an alias for *which* such as the following:

```
$alias which
alias which='alias | /usr/bin/which --tty-only --read-alias --show-dot --show-tilde'
```

If *which* is not behaving as you would expect, verify that you are not running an alias. The preceding alias causes *which* to be effective only when it is run interactively (`tty-only`) and to display aliases, display the working directory as a period when appropriate, and display the name of the user's home directory as a tilde.

The TC Shell includes a *which* builtin (see the *tcsh* man page) that works slightly differently from the *which* utility (/usr/bin/which). Without any options the *which* utility does not locate aliases, functions, and shell builtins because these do not appear in *PATH*. In contrast the *tcsh* *which* builtin locates aliases, functions, and shell builtins.

Examples

The first example quotes the first letter of the command (*which*) to prevent the shell from invoking the alias (page
for which:

$ \texttt{\textbackslash which} \texttt{vim} \texttt{dir} \texttt{which}

/usr/bin/vim
/usr/bin/dir
/usr/bin/which

The next example is the same as the first but uses the alias for which (which it displays):

$ \texttt{which} \texttt{vim} \texttt{dir} \texttt{which}

alias which='\texttt{alias} | /usr/bin/which --tty-only --read-alias --show-dot --show-tilde'

/usr/bin/which
/usr/bin/vim
/usr/bin/dir

The final example is the same as the previous one except that it is run from tcsh. The tcsh which builtin is used instead of the which utility:

tcsh $ \texttt{which} \texttt{vim} \texttt{dir} \texttt{which}

/usr/bin/vim
/usr/bin/dir

which: shell built-in command.

who: Displays information about logged-in users

who [options]
who am i

The who utility displays information about users who are logged in on the local system. This information includes each user's username, terminal device, login time, and, if applicable, the corresponding remote hostname or X display.

Arguments
When given two arguments (traditionally, `am i`), `who` displays information about the user giving the command. If applicable, the username is preceded by the hostname of the system running `who` (as in `kudos!alex`).

### Options

Accepts the common options described on page 587.

- `all` Displays a lot of information.
- `boot` Displays the date and time the system was last booted.
- `heading` Displays a header.
- `login` (lowercase "l") Lists devices waiting for a user to log in.
- `count` Lists the usernames only, followed by the number of users logged in on the system.
- `message` or `mesg` Appends after each user's username a character that shows whether that user has messages enabled. A plus (+) means that messages are enabled, a hyphen (-) means that they are disabled, and a question mark (?) indicates that `who` cannot find the device. If messages are enabled, you can use `write` to communicate with the user. Refer to "mesg: Denies or Accepts Messages" on page 68.
- `users` Includes each user's idle time in the display. If the user has typed on her terminal in the past minute, a period (.) appears in this field. If no input has occurred for more than a day, the word `old` appears. In addition, this option includes the PID number and comment fields. See "Discussion."

### Discussion

The line that `who` displays has the following syntax:

```
user [messages] line login-time [idle] [PID] comment
```

The `user` is the username of the user. The `messages` indicates whether messages are enabled or disabled (see the `message` option). The `line` is the device name associated with the line the user is logged in on. The `login-time` is the date and time that the user logged in. The `idle` is the length of time since the terminal was last used (the `idle time`; see the `idle` option). The `PID` is the process identification number. The `comment` is the remote system or X display that the user is logged in from (blank for local users).

### Notes

The `finger` utility (page 661) provides information similar to that given by `who`.

### Examples

The following examples demonstrate the use of the `who` utility:

```
$ who
hls  tty1  Jul 30 06:01
```
xargs: Converts standard input into command lines

xargs [options] [command]

The `xargs` utility is a convenient, efficient way to convert standard output of one command into arguments for another command. This utility reads from standard input, keeps track of the maximum allowable length of a command line, and avoids exceeding that limit by repeating `command` as needed. Finally `xargs` executes the constructed command line.

Arguments

The `command` is the command line you want `xargs` to use as a base for the command it constructs. If you omit `command`, it defaults to `echo`. The `xargs` utility appends to `command` the arguments it receives from standard input. If any arguments should precede the arguments from standard input, you must include them as part of `command`.

Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-replace[=marker]</code></td>
<td>Allows you to place arguments from standard input anywhere within <code>command</code>. All occurrences of <code>marker</code> in <code>command</code> for <code>xargs</code> are replaced by the arguments generated from standard input of <code>xargs</code>. If you omit <code>marker</code>, it defaults to the string <code>{}</code>, which matches the syntax used in the <code>find</code> command's <code>exec</code> option. With this option <code>command</code> is executed for each input line; the <code>-max-lines</code> option limits the number of lines in the output.</td>
</tr>
</tbody>
</table>

| `-i [ marker ]` |  |

$ who am i
bravo!alex ttyp3 Jul 30 14:56 (bravo)

$ who --heading --users -T

<table>
<thead>
<tr>
<th>USER</th>
<th>LINE</th>
<th>TIME</th>
<th>IDLE</th>
<th>PID</th>
<th>COMMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>hls</td>
<td>-</td>
<td>tty1</td>
<td>Jul 30 06:01 03:53</td>
<td>1821</td>
<td></td>
</tr>
<tr>
<td>jenny</td>
<td>+</td>
<td>tty2</td>
<td>Jul 30 06:02 14:47</td>
<td>2235</td>
<td></td>
</tr>
<tr>
<td>alex</td>
<td>+</td>
<td>ttyp3</td>
<td>Jul 30 14:56 .</td>
<td>14777</td>
<td>(bravo)</td>
</tr>
</tbody>
</table>
option is ignored when you use `replace`.

```
maxlines=num
```

```
[l num]
```
(lowercase "l") Executes `command` once for every `num` lines of input (`num` defaults to 1).

```
maxargs=num
```

```
l [ num ]
```
Executes `command` once for every `num` arguments in the input line.

```
interactive [p]
```
Prompts the user prior to each execution of `command`.

```
maxprocs=num
```

```
P [ num ]
```
Allows `xargs` to run up to `maxprocs` instances of `command` simultaneously. (The default is 1, which runs `command` s sequentially.) This option may improve the throughput if you are running Linux on a multiprocessor system.

```
no-runif-empty
```

```
r
```
Causes `xargs` not to execute `command` if standard input is empty. Ordinarily `xargs` executes `command` at least once, even if standard input includes only blanks.

**Discussion**

The `xargs` utility reads arguments to `command` from standard input, interpreting each whitespace-delimited string as a separate argument. It then constructs a command line from `command` and a series of arguments. When the maximum command line length would be exceeded by adding another argument, `xargs` runs the command line it has built. If there is more input, `xargs` repeats the process of building a command line and running it. This process continues until all input has been read.

**Notes**

One common use of `xargs` is as an efficient alternative to the `exec` option of `find` (page 656). If you call `find` with the `exec` option to run a command, it runs the command once for each file it processes. Each execution of the command creates a new process, which can drain system resources when you are processing many files. By accumulating as many arguments as possible, `xargs` can greatly reduce the number of processes needed. The first example in the "Examples" section shows how to use `xargs` with `find`.

The `replace` option changes how `xargs` handles whitespace in standard input. Without this option, `xargs` treats sequences of blanks, TABS, and NEWLINES as equivalent. With this option, `xargs` TReats NEWLINE characters in a special way. If it encounters a NEWLINE in standard input when using the `replace` option, `xargs` runs
**command** using the argument list that has been built up to that point.

**Examples**

To locate and remove all files whose names end in *.o from the working directory and its subdirectories, you can use the **find exec** option:

```
$ find . -name \.o -exec rm --force {} \;
```

This approach calls the **rm** utility once for each .o file that **find** locates. Each invocation of **rm** requires a new process. If a lot of .o files exist, a significant amount of time is spent creating, starting, and then cleaning up these processes. You can reduce the number of processes by allowing **xargs** to accumulate as many filenames as possible before calling **rm**:

```
$ find . -name \.o -print | xargs rm --force
```

In the next example, the contents of all *.txt files located by **find** are searched for lines containing the word **login**. All filenames that contain **login** are displayed by **grep**:

```
$ find . -name \.txt -print | xargs grep -w -l login
```

The next example shows how you can use the **replace** option to cause **xargs** to embed standard input within **command** instead of appending it to **command**. This option also causes **command** to be executed each time a NEWLINE character is encountered in standard input; **max-lines** does not override this behavior.

```
$ cat names
Tom,
Dick,
and Harry
$ xargs echo "Hello, " < names
Hello, Tom, Dick, and Harry
$ xargs --replace echo "Hello {}. Join me for lunch?" < names
Hello Tom,. Join me for lunch?
Hello Dick,. Join me for lunch?
Hello and Harry. Join me for lunch?
```

The final example uses the same input file as the previous example as well as the **max-args** and **max-lines** options:
$ xargs echo "Hi there" < names
Hi there Tom, Dick, and Harry

$ xargs --max-args=1 echo "Hi there" < names
Hi there Tom,
Hi there Dick,
Hi there and
Hi there Harry

$ xargs --max-lines=2 echo "Hi there" < names
Hi there Tom, Dick,
Hi there and Harry

See page 775 for another example of the use of xargs.
Part VI: Appendixes

APPENDIX A Regular Expressions
APPENDIX B Help
APPENDIX C Keeping The System Up-To-Date
Appendix A. Regular Expressions

IN THIS APPENDIX

Characters 828
Delimiters 828
Simple Strings 828
Special Characters 828
Rules 831
Bracketing Expressions 832
The Replacement String 833
Extended Regular Expressions 834

A regular expression defines a set of one or more strings of characters. A simple string of characters is a regular expression that defines one string of characters: itself. A more complex regular expression uses letters, numbers, and special characters to define many different strings of characters. A regular expression is said to match any string it defines.

This appendix describes the regular expressions used by ed, vim, emacs, grep, gawk, sed, and other utilities. The regular expressions used in shell ambiguous file references are different and are described in "Filename Generation/Pathname Expansion" on page 127.
Characters

As used in this appendix, a character is any character except a NEWLINE. Most characters represent themselves within a regular expression. A special character is one that does not represent itself. If you need to use a special character to represent itself, you must quote it as explained on page 831.
Delimiters

A character called a *delimiter* usually marks the beginning and end of a regular expression. The delimiter is always a special character for the regular expression it delimits (that is, it does not represent itself but marks the beginning and end of the expression). Although *vim* permits the use of other characters as a delimiter and *grep* does not use delimiters at all, the regular expressions in this appendix use a forward slash (/) as a delimiter. In some unambiguous cases, the second delimiter is not required. For example, you can sometimes omit the second delimiter when it would be followed immediately by RETURN.
Simple Strings

The most basic regular expression is a simple string that contains no special characters except the delimiters. A simple string matches only itself (Table A-1). In the examples in this appendix, the strings that are matched are underlined and **look like this**.

<table>
<thead>
<tr>
<th>Regular expression</th>
<th>Matches</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>/ring/</td>
<td>ring</td>
<td>ring, spring, ringing, stringing</td>
</tr>
<tr>
<td>/Thursday/</td>
<td>Thursday</td>
<td>Thursday, Thursday's</td>
</tr>
<tr>
<td>/or not/</td>
<td>or not</td>
<td>or not, poor nothing</td>
</tr>
</tbody>
</table>
Special Characters

You can use special characters within a regular expression to cause the regular expression to match more than one string. A regular expression that includes a special character always matches the longest possible string, starting as far toward the beginning (left) of the line as possible.

Periods

A period (.) matches any character (Table A-2).

<table>
<thead>
<tr>
<th>Table A-2. Period</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Regular expression</td>
<td>Matches</td>
<td>Examples</td>
</tr>
<tr>
<td>/. .alk/</td>
<td>All strings consisting of a SPACE followed by any character followed by alk</td>
<td>will talk, may balk</td>
</tr>
<tr>
<td>/. .ing/</td>
<td>All strings consisting of any character preceding ing</td>
<td>sing song, ping, before inglenook</td>
</tr>
</tbody>
</table>

Brackets

Brackets ([ ]) define a character class (1) that matches any single character within the brackets (Table A-3). If the first character following the left bracket is a caret (^), the brackets define a character class that matches any single character not within the brackets. You can use a hyphen to indicate a range of characters. Within a character-class definition, backslashes and asterisks (described in the following sections) lose their special meanings. A right bracket (appearing as a member of the character class) can appear only as the first character following the left bracket. A caret is special only if it is the first character following the left bracket. A dollar sign is special only if it is followed immediately by the right bracket.

[1] GNU documentation calls these List Operators and defines Character Class operators as expressions that match a predefined group of characters, such as all numbers (see Table V-28 on page 804).

<table>
<thead>
<tr>
<th>Table A-3. Brackets</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Regular expression</td>
<td>Matches</td>
<td>Examples</td>
</tr>
<tr>
<td>/[bB]ill/</td>
<td>Member of the character class b and B followed by ill</td>
<td>bill, Bill, billed</td>
</tr>
<tr>
<td>/[aeiou].k/</td>
<td>l followed by a lowercase vowel, any character, and a k</td>
<td>talkative, stink, teak, tanker</td>
</tr>
<tr>
<td>/# [69]/</td>
<td># followed by a SPACE and a member of the character class 6 through 9</td>
<td># 60, # 8:, get # 9</td>
</tr>
<tr>
<td>/[^a-zA-Z]/</td>
<td>Any character that is not a letter (ASCII character set only)</td>
<td>1, 7, @, ., _, Stop!</td>
</tr>
</tbody>
</table>

Asterisks

An asterisk can follow a regular expression that represents a single character (Table A-4). The asterisk represents zero or more occurrences of a match of the regular expression. An asterisk following a period matches any string of characters. (A period matches any character, and an asterisk matches zero or more occurrences of the preceding regular expression.) A character-class definition followed by an asterisk matches any string of characters that are members of the character class.
Table A-4. Asterisks

<table>
<thead>
<tr>
<th>Regular expression</th>
<th>Matches</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>/ab*c/</td>
<td>a followed by zero or more b's followed by a c</td>
<td>ac, abc, abbc, debbcaabbbc</td>
</tr>
<tr>
<td>/ab.*c/</td>
<td>ab followed by zero or more characters followed by c</td>
<td>abc, abxc, ab45c, xab 756.345 x cat</td>
</tr>
<tr>
<td>/t.ing/</td>
<td>t followed by zero or more characters followed by ing</td>
<td>thing, ting, I thought of going</td>
</tr>
<tr>
<td>/[a-zA-Z ]*/</td>
<td>A string composed only of letters and SPACEs</td>
<td>1, any string without numbers or punctuation!</td>
</tr>
<tr>
<td>/([.]*)/</td>
<td>As long a string as possible between ( and )</td>
<td>Get (this) and (that);</td>
</tr>
<tr>
<td>/([{}])/*/</td>
<td>The shortest string possible that starts with { and ends with }</td>
<td>(this), Get (this and that)</td>
</tr>
</tbody>
</table>

Carets and Dollar Signs

A regular expression that begins with a caret (^) can match a string only at the beginning of a line. In a similar manner, a dollar sign ($) at the end of a regular expression matches the end of a line. The caret and dollar sign are called anchors because they force (anchor) a match to the beginning or end of a line (Table A-5).

Table A-5. Carets and dollar signs

<table>
<thead>
<tr>
<th>Regular expression</th>
<th>Matches</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>^T/</td>
<td>A T at the beginning of a line</td>
<td>This line...,</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>^+[09]/</td>
<td>A plus sign followed by a digit at the beginning of a line</td>
<td>+5, 45.72,</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>:$/</td>
<td>A colon that ends a line</td>
<td>...below:$</td>
</tr>
</tbody>
</table>

Quoting Special Characters

You can quote any special character (but not a digit or a parenthesis) by preceding it with a backslash (Table A-6). Quoting a special character makes it represent itself.

Table A-6. Quoted special characters

<table>
<thead>
<tr>
<th>Regular expression</th>
<th>Matches</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>/end ./</td>
<td>All strings that contain end followed by a period</td>
<td>The end, send, pretend, mail</td>
</tr>
<tr>
<td>/\</td>
<td>A single backslash</td>
<td>\</td>
</tr>
<tr>
<td>/*</td>
<td>An asterisk</td>
<td><em>.c, an asterisk (</em>)</td>
</tr>
<tr>
<td>/[5]/</td>
<td>[5]</td>
<td>it was five [5]</td>
</tr>
<tr>
<td>/and/or /</td>
<td>and/or</td>
<td>and/or</td>
</tr>
</tbody>
</table>
Rules

The following rules govern the application of regular expressions.

Longest Match Possible

A regular expression always matches the longest possible string, starting as far toward the beginning of the line as possible. For example, given the string

This (rug) is not what it once was (a long time ago), is it?

the expression /Th.*is/ matches

This (rug) is not what it once was (a long time ago), is

and /(.*)/ matches

(rug) is not what it once was (a long time ago)

However, /(^[)])*/ matches

(rug)

Given the string

singing songs, singing more and more

the expression /s.*ing/ matches

singing songs, singing

and /s.*ing song/ matches

singing song

Empty Regular Expressions

Within some utilities, such as vim and less (but not grep), an empty regular expression represents the last
regular expression that you used. For example, suppose you give `vim` the following Substitute command:

```
:s/mike/robert/
```

If you then want to make the same substitution again, you can use the following command:

```
:s//robert/
```

Alternatively, you can use the following commands to search for the string `mike` and then make the substitution

```
/mike/
:s//robert/
```

The empty regular expression (`//`) represents the last regular expression you used (`/mike/`).
Bracketing Expressions

You can use quoted parentheses, \( \) and \), to bracket a regular expression. The string that the bracketed regular expression matches can be recalled, as explained in "Quoted Digit." A regular expression does not attempt to match quoted parentheses. Thus a regular expression enclosed within quoted parentheses matches what the same regular expression without the parentheses would match. The expression \(/(\text{rexp})/\) matches what \(/\text{rexp}/\) would match; \(/\text{a}(\text{b}*)\text{c}/\) matches what \(/\text{ab}^*\text{c}/\) would match.

You can nest quoted parentheses. The bracketed expressions are identified only by the opening \(, so no ambiguity arises in identifying them. The expression \(/([a-z][A-Z]*)x)/\) consists of two bracketed expressions, one nested within the other. In the string \(3 \ t \ dMNORx7 \ u,\) the preceding regular expression matches \(dMNORx,\) with the first bracketed expression matching \(dMNORx\) and the second matching \(MNOR.\)
The Replacement String

The `vim` and `sed` editors use regular expressions as search strings within Substitute commands. You can use the ampersand (`&`) and quoted digits (\texttt{\textbackslash n}) special characters to represent the matched strings within the corresponding replacement string.

Ampersand

Within a replacement string, an ampersand (`&`) takes on the value of the string that the search string (regular expression) matched. For example, the following `vim` Substitute command surrounds a string of one or more digits with \texttt{NN}. The ampersand in the replacement string matches whatever string of digits the regular expression (search string) matched:

```
:s/\[0-9\]\[0-9\]*/NN&NN/
```

Two character-class definitions are required because the regular expression \texttt{[0-9]*} matches \texttt{zero} or more occurrences of a digit, and \texttt{any} character string constitutes zero or more occurrences of a digit.

Quoted Digit

Within the search string, a bracketed regular expression, \texttt{\(xxx\)}, matches what the regular expression would have matched without the quoted parentheses, \texttt{xxx}. Within the replacement string, a quoted digit, \texttt{\textbackslash n}, represents the string that the bracketed regular expression (portion of the search string) beginning with the \texttt{n}th \texttt{\} matched. For example, you can take a list of people in the form

\texttt{last-name, first-name initial}

and put it in the form

\texttt{first-name initial last-name}

with the following `vim` command:

```
:1,$s/\([\^,]*\), \(.*\))/\2 \1/
```

This command addresses all the lines in the file \texttt{(1,$)}. The Substitute command (\texttt{s}) uses a search string and a replacement string delimited by forward slashes. The first bracketed regular expression within the search string, \texttt{\([\^,]*\)}, matches what the same unbracketed regular expression, \texttt{\^[,]*}, would match: zero or more characters not containing a comma (the \texttt{last-name}). Following the first bracketed regular expression are a comma and a SPACE that match themselves. The second bracketed expression, \texttt{\((.*\))}, matches any string of characters (the \texttt{first-name} and \texttt{initial}).

The replacement string consists of what the second bracketed regular expression matched (\texttt{\2}), followed by a SPACE and what the first bracketed regular expression matched (\texttt{\1}).
**Extended Regular Expressions**

The three utilities `egrep`, `grep` when run with the `E` option (similar to `egrep`), and `gawk` provide all the special characters that are included in ordinary regular expressions, except for `\(` and `\)`, as well as several others. The `vim` editor includes the additional characters as well as `\(` and `\)`. Patterns using the extended set of special characters are called *full regular expressions* or *extended regular expressions*.

Two of the additional special characters are the plus sign (+) and the question mark (?). They are similar to *, which matches zero or more occurrences of the previous character. The plus sign matches one or more occurrences of the previous character, whereas the question mark matches zero or one occurrence. You can use any one of the special characters *, +, and ? following parentheses, causing the special character to apply to the string surrounded by the parentheses. Unlike the parentheses in bracketed regular expressions, these parentheses are not quoted (Table A-7).

<table>
<thead>
<tr>
<th>Table A-7. Extended regular expressions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Regular expression</strong></td>
</tr>
<tr>
<td>/ab+c/</td>
</tr>
<tr>
<td>/ab?c/</td>
</tr>
<tr>
<td>/(ab)+c/</td>
</tr>
<tr>
<td>/(ab)?c/</td>
</tr>
</tbody>
</table>

In full regular expressions, the vertical bar (|) special character is a Boolean OR operator. Within `vim`, you must quote the vertical bar by preceding it with a backslash to make it special (\|). A vertical bar between two regular expressions causes a match with strings that match the first expression, the second expression, or both. You can use the vertical bar with parentheses to separate from the rest of the regular expression the two expressions that are being ORed (Table A-8).

<table>
<thead>
<tr>
<th>Table A-8. Full regular expressions</th>
</tr>

<tr>
<td>/(D</td>
</tr>
</tbody>
</table>
Appendix Summary

A regular expression defines a set of one or more strings of characters. A regular expression is said to match any string it defines.

In a regular expression, a special character is one that does not represent itself. Table A-9 lists special characters.

### Table A-9. Special characters

<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>Matches any single character</td>
</tr>
<tr>
<td>*</td>
<td>Matches zero or more occurrences of a match of the preceding character</td>
</tr>
<tr>
<td>^</td>
<td>Forces a match to the beginning of a line</td>
</tr>
<tr>
<td>$</td>
<td>A match to the end of a line</td>
</tr>
<tr>
<td>\</td>
<td>Used to quote special characters</td>
</tr>
<tr>
<td>&lt;</td>
<td>Forces a match to the beginning of a word</td>
</tr>
<tr>
<td>&gt;</td>
<td>Forces a match to the end of a word</td>
</tr>
</tbody>
</table>

Table A-10 lists ways of representing character classes and bracketed regular expressions.

### Table A-10. Character classes and bracketed regular expressions

<table>
<thead>
<tr>
<th>Class</th>
<th>Defines</th>
</tr>
</thead>
<tbody>
<tr>
<td>[xyz ]</td>
<td>Defines a character class that matches (x, y,) or (z)</td>
</tr>
<tr>
<td>[^xyz ]</td>
<td>Defines a character class that matches any character except (x, y,) or (z)</td>
</tr>
<tr>
<td>[x\d z ]</td>
<td>Defines a character class that matches any character (x) through (z) inclusive</td>
</tr>
<tr>
<td>( x y z )</td>
<td>Matches what (xyz) matches (a bracketed regular expression)</td>
</tr>
</tbody>
</table>

In addition to the preceding special characters and strings (excluding quoted parentheses, except in `vim`), the characters given in Table A-11 are special within full, or extended, regular expressions.

### Table A-11. Extended regular expressions

<table>
<thead>
<tr>
<th>Expression</th>
<th>Matches</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Matches one or more occurrences of the preceding character</td>
</tr>
<tr>
<td>?</td>
<td>Matches zero or one occurrence of the preceding character</td>
</tr>
<tr>
<td>(xyz )+</td>
<td>One or more occurrences of what (xyz) matches</td>
</tr>
<tr>
<td>(xyz )?</td>
<td>Zero or one occurrence of what (xyz) matches</td>
</tr>
<tr>
<td>(xyz )*</td>
<td>Zero or more occurrences of what (xyz) matches</td>
</tr>
<tr>
<td>(xy\</td>
<td>abc)</td>
</tr>
<tr>
<td>(xy\</td>
<td>ab)c)</td>
</tr>
</tbody>
</table>

Table A-12 lists characters that are special within a replacement string in `sed` and `vim`.
<table>
<thead>

Solving a Problem 838
Finding Linux-Related Information 839
Documentation 839
Useful Linux Sites 840
Linux Newsgroups 841
Mailing Lists 841
Words 841
Software 842
Office Suites and Word Processors 844
Specifying a Terminal 844

You need not act as a user or system administrator in isolation. A large community of Linux experts is willing to assist you in learning about, helping you solve your problems with, and getting the most out of your Linux system. Before you ask for help, however, make sure you have done everything you can to solve the problem by yourself. No doubt, someone has experienced the same problem before you and the answer to your question can be found somewhere on the Internet. Your job is to find it. This appendix lists resources and describes methods that can help you in that task.
Solving A Problem

Following is a list of steps that can help you solve a problem without asking someone else for help. Depending on your understanding of and experience with the hardware and software involved, these steps may lead to a solution.

1. Most Linux distributions come with extensive documentation. Read the documentation on the specific hardware or software you are having a problem with. If it is a GNU product, use info; otherwise, use man to find local information. For more information refer to "Getting the Facts: Where to Find Documentation" on page 29.

2. When the problem involves some type of error or other message, use a search engine, such as Google (www.google.com) or Google Groups (groups.google.com), to look up the message on the Internet. If the message is long, pick a unique part of the message to search for; 10 to 20 characters should be enough. Enclose the search string within double quotation marks.

3. Check whether the Linux Documentation Project (www.tldp.org) has a HOWTO or mini-HOWTO on the subject in question. Search on keywords that relate directly to the product and your problem. Read the FAQs.

4. See Table B-1 for other sources of documentation.

<td>Request for Comments; see RFCs</td>
<td><a href="http://www.rfc-editor.org">www.rfc-editor.org</a></td>
</tr>
</tbody>
</table>
5. Use Google or Google Groups to search on keywords that relate directly to the product and your problem.

6. When all else fails (or perhaps before you try anything else) examine the system logs in `/var/log`. Running as Superuser, first look at the end of the `messages` file using the following command:

```
# tail -20 /var/log/messages
```

If `messages` contains nothing useful, run the following command. It displays the names of the log files in chronological order, with the most recently modified files appearing at the bottom of the list:

```
$ ls -ltr /var/log
```

If your problem involves a network connection, review the `secure` log file (some systems may use a different name) on the local and remote systems. Also look at `messages` on the remote system.

7. The `/var/spool` directory contains subdirectories with useful information: `cups` holds the print queues, `mail` holds the user's mail files, and so on.

If you are unable to solve a problem yourself, a thoughtful question to an appropriate newsgroup (page 841) or mailing list (page 841) can elicit useful information. When you send or post a question, make sure you describe the problem and identify the local system carefully. Include the version numbers of the operating system and any software packages that relate to the problem. Describe your hardware, if appropriate.

The author's home page (www.sobell.com) contains corrections to this book, answers to selected chapter exercises, and pointers to other Linux sites.
Finding Linux-Related Information

Distributions of Linux come with reference pages stored online. You can read these documents by using the info (page 32) or man (page 30) utilities. You can read man and info pages to get more information about specific topics while reading this book or to determine which features are available with Linux. You can search for topics by using apropos (see page 62 or give the command man apropos).

Documentation

Good books are available on various aspects of using and administrating UNIX systems in general and Linux systems in particular. In addition, you may find the sites listed in Table B-1 useful.[1]

[1] The right-hand columns of most of the tables in this appendix show Internet addresses (URLs). All sites have an implicit http:// prefix unless ftp:// or https:// is shown. Refer to "URLs (Web addresses)" on page 23.

Useful Linux Sites

Sometimes the sites listed in Table B-2 are so busy that you cannot log in. When this happens, you are usually given a list of alternative, or mirror, sites to try.

Linux Newsgroups

One of the best ways of getting specific information is through a newsgroup. Frequently you can find the answer to your question by reading postings to the newsgroup. Try using Google Groups (groups.google.com) to search through newsgroups to see whether your question has already been asked and answered. Or open a newsreader program and subscribe to appropriate newsgroups. If necessary, you can post your question for someone to answer. Before you do so, make sure you are posting to the correct group and that your question has not been answered.
There is an etiquette to posting questions; see www.catb.org/~esr/faqs/smart-questions.html for a good paper by Eric S. Raymond and Rick Moen titled "How To Ask Questions the Smart Way."

The newsgroup comp.os.linux.answers provides postings of solutions to common problems and periodic postings of the most up-to-date versions of the FAQ and HOWTO documents. The comp.os.linux.misc newsgroup has answers to miscellaneous Linux-related questions.

Mailing Lists

Subscribing to a mailing list allows you to participate in an electronic discussion. With most lists, you can send and receive email dedicated to a specific topic to and from a group of users. Moderated lists do not tend to stray as much as unmoderated lists, assuming the list has a good moderator. The disadvantage of a moderated list is that some discussions may be cut off when they get interesting if the moderator deems that the discussion has gone on for too long. Mailing lists described as bulletins are strictly unidirectional: You cannot post information to these lists but can only receive periodic bulletins. If you have the subscription address for a mailing list but are not sure how to subscribe, put the word help in the body and/or header of email that you send to the address. You will usually receive instructions via return email. You can also use a search engine to search for mailing list linux.

Words

Many dictionaries, thesauruses, and glossaries are available online. Table B-3 lists a few of them.

<table>
<thead>
<tr>

Specifying a Terminal

Because vim, emacs, konsole, and other programs take advantage of features that are specific to various kinds of terminals and terminal emulators, you must tell these programs the name of the terminal you are using or the terminal that your terminal emulator is emulating. On many systems your terminal name is set for you. If your terminal name is not specified or is not specified correctly, your screen will look garbled or, when you start a program, the program will ask what type of terminal you are using.

Terminal names describe the functional characteristics of your terminal or terminal emulator to programs that require this information. Although terminal names are referred to as either Terminfo or Termcap names, the difference relates to the method that each system uses to store the terminal characteristics internally, not in the manner that you specify the name of a terminal. Terminal names that are often used with Linux terminal emulators and with graphical monitors while they are run in text mode are ansi, linux, vt100, vt102, vt220, and xterm.

When you are running a terminal emulator, you can specify the type of terminal you want to emulate. Set the emulator to either vt100 or vt220, and set TERM to the same value.

When you log in, you may be prompted to identify the type of terminal you are using:

TERM = (vt100)

There are two ways to respond to this prompt. You can press RETURN to set your terminal type to the name in parentheses. When that name does not describe the terminal you are using, you can enter the correct name and then press RETURN.

TERM = (vt100) ansi

You may also receive the following prompt:

TERM = (unknown)

This prompt indicates that the system does not know what type of terminal you are using. If you plan to run programs that require this information, enter the name of the terminal or terminal emulator you are using before you press RETURN.

TERM

If you do not receive a prompt, you can give the following command to display the value of the TERM variable and check whether your terminal type has been set:

$ echo $TERM

If the system responds with the wrong name, a blank line, or an error message, set or change the terminal name. From the Bourne Again Shell (bash), enter a command similar to the following to set the TERM variable so that the system knows the type of terminal you are using:
export TERM=name

Replace name with the terminal name for the terminal you are using, making sure that you do not put a SPACE before or after the equal sign. If you always use the same type of terminal, you can place this command in your ~/.bashrc file (page 257), causing the shell to set the terminal type each time you log in. For example, give the following command to set your terminal name to vt100:

    $ export TERM=vt100

Use the following format under the TC Shell (tcsh).

setenv TERM name

Again replace name with the terminal name for the terminal you are using. Under tcsh you can place this command in your ~/.login file (page 342). For example, under tcsh you can give this command to set your terminal name to vt100:

    $ setenv TERM vt100

LANG

For some programs to display information correctly you may need to set the LANG variable (page 290). Frequently you can set this variable to C. Under bash use the command

    $ export LANG=C

and under tcsh use

    $ setenv LANG C
Appendix C. Keeping The System Up-To-Date

IN THIS APPENDIX

yum: Updates and Installs Packages 848

Apt: An Alternative to yum 850

BitTorrent 855

Apt and yum both fill the same role: They install and update software packages. Both utilities compare the files in a repository (generally on the Internet) with those on the local system and update the files on the local system according to your instructions. Both utilities automatically install and update any additional files that a package is dependent on. Apt is slightly faster, especially over slow connections, and it supports a few more features, such as undoing upgrades. The yum utility is easier to configure and use than Apt. If you are familiar with Debian systems or find that yum lacks some features you need, try using Apt; otherwise use yum. The examples in this section are from a Fedora Core system; although the files, input, and output on your system may look different, how you use the tools and the results will be the same.

Contrasted with Apt and yum, BitTorrent efficiently distributes large amounts of static data, such as installation ISO images. It does not check files on the local system and does no dependency checking.
**yum: Updates And Installs Packages**

Early releases of Linux did not include a tool for managing updates. The RPM tool could install or upgrade individual software packages, but it was up to the user to locate the packages and the packages they were dependent on. When Terra Soft produced its Linux distribution for the PowerPC, the company created the Yellow Dog Updater to fill this gap. This program has since been ported to other architectures and distributions. The result, named Yellow Dog Updater, Modified *(yum)*, is included with many Linux distributions. The *yum* home page is [linux.duke.edu/projects/yum](http://linux.duke.edu/projects/yum) and more information is available at [apt.freshrpms.net](http://apt.freshrpms.net).

**Configuring yum**

The *yum* utility is designed to be easy to use. The configuration file, */etc/yum.conf*, has two parts: The **[main]** section contains general settings and the rest of the file holds a list of servers.

The **[main]** section must be present for *yum* to function. The **cachedir** specifies the directory *yum* uses to store downloaded packages and **logfile** specifies where *yum* keeps its log. The amount of information logged is specified by **debuglevel**, with a value of 10 producing the most information.

```bash
$ cat /etc/yum.conf

[main]
cachedir=/var/cache/yum
debuglevel=2
logfile=/var/log/yum.log
pkgpolicy=newest
distroverpkg=fedora-release
tolerant=1
exactarch=1
...
```

The **pkgpolicy** defines which version of a software package *yum* installs; always set it to **newest** to install the newest version of a package. You can also configure *yum* to try to install from a specific server, falling back to other servers on failure and ignoring package versions. The **distroverpkg** specifies which distribution the system is running.

With **tolerant** set to **1**, *yum* automatically corrects simple command line errors, such as attempting to install a package already on the system. Setting **tolerant** to **0** turns this feature off. Setting **exactarch** to **1** causes *yum* to update packages only with packages of the same architecture, preventing an i686 package from replacing an i386 one, for example.

The last sections contain lists of servers holding updates. They are marked with **[core]**, **[updates]**, or other similar labels. Frequently the last section contains updates that are not ready for release and is commented out; do not
uncomment it unless you are testing unstable packages. Never uncomment this section on production systems. Each server section contains a name, baseurl, and gpgcheck flag:

```
$ cat /etc/yum.conf
...
[core]
name=Fedora Linux $releasever - $basearch - core
baseurl=http://ayo.freshrpms.net/fedora/linux/$releasever/$basearch/core
gpgcheck=1
...
```

The name provides a friendly name for the server. The baseurl indicates the location of the server. Set gpgcheck to 1 if you want yum to check the gpg signatures of the packages it downloads. Set it to 0 otherwise. These definitions use two variables: yum sets $basearch to the architecture of the system and $releasever to the version of the release. Refer to the yum.conf man page for more options.

**Using yum**

Working as root, you can run yum from a command line. Its behavior depends on the options you specify. The update option updates all installed packages: It downloads package headers for installed packages, prompts you to proceed, and downloads and installs the updated packages.

```
# yum update
Gathering header information file(s) from server(s)
Server: Fedora Core 3 - i386 - Base
Server: Fedora Core 3 - i386 - Released Updates
Finding updated packages
Downloading needed headers
getting /var/cache/yum/updates-released/headers/pango-0-1.6.07.i386.hdr
pango-0-1.6.0-7.i386.hdr 100% |=================================| 6.5 kB 00:00
...
[update: rhn-applet 2.1.4-3.i386]
Is this ok [y/N]: y
```
Getting pango-1.6.0-7.i386.rpm

pango-1.6.0-7.i386.rpm    100% |=========================| 341 kB 00:06

... 

You can update individual packages by specifying the names of the packages on the command line following the word update.

To install a new package together with the packages it is dependent on, give the command yum install followed by the name of the package as shown on the next page.

# yum install tcsh

Gathering header information file(s) from server(s)

APT: An Alternative To yum

The Apt (Advanced Package Tool) utility can help with the issue of dependencies: Apt tries to resolve package dependencies automatically by looking for the packages that the package you are installing is dependent on. Since starting life as part of the Debian Linux distribution using Debian's .deb package format, Apt has been ported to rpm-based distributions. For more information go to apt.freshrpms.net.

The Apt utility uses repositories of rpm files as the basis for its actions. To make things quicker, Apt keeps locally a list of packages that are held in each of the repositories it uses. Any software you want to install or update must reside in a repository.

When you give Apt a command to install a package, Apt looks for the package in its local package list. If the package appears in the list, Apt fetches both that package and any packages that the package you are installing is dependent on and calls rpm to install the packages. Because Apt uses rpm, it maintains the rpm database.

Using Apt

This section describes how to configure Apt.

INSTALLING AND SETTING UP APT

Once you have downloaded the apt.rpm file, you must install it (your Apt version number will be different):

```
# rpm -Uvh apt-0.5.15cnc6-1.1.fc3.fr.i386.rpm
Preparing... ###########################################[100%]
1:apt               ###########################################[100%]
```

Update the local package list

The primary Apt command is apt-get; its arguments determine what the command does. After you install Apt, give the command apt-get update to update the local package list:

```
# apt-get update
Fetched 1991B in 0s (4922B/s)
Get:1 http://ayo.freshrpms.net fedora/linux/3/i386/core pkglist [1445kB]
Get:2 http://ayo.freshrpms.net fedora/linux/3/i386/core release [151B]
Get:3 http://ayo.freshrpms.net fedora/linux/3/i386/updates pkglist [251kB]
Get:4 http://ayo.freshrpms.net fedora/linux/3/i386/updates release [157B]
```
Because the available packages change frequently, it is a good idea to create a `cron` job to update the local package list automatically. Create the following file to perform this task daily:

```bash
$ cat /etc/cron.daily/apt-update
apt-get update
```

The Apt utility does not tolerate a broken `rpm` dependency tree. To check the status of the local dependency tree, run `apt-get check`:

```bash
# apt-get check
```

The easiest way to fix errors that `apt-get` reveals is to erase the offending packages and then reinstall them using Apt.

At the time this book was written, Apt was incompatible with the Ximian Desktop.

**Update the system**

Two arguments to `apt-get` cause it upgrade all packages on the system: `upgrade` upgrades all packages on the system that do not require new packages to be installed and `dist-upgrade` upgrades all packages on the system, installing new packages as needed.

The following command updates all `rpm`-based packages on the system that depend only on packages that are already installed:

```bash
# apt-get upgrade
```
Reading Package Lists... Done
Building Dependency Tree... Done
The following packages will be upgraded
    bash binutils dia ethereal foomatic gaim gdm ghostscript gimp-print ...
    rhn-applet rsync sed slocate strace vnc-server yum
The following packages have been kept back
    gstreamer-plugins gthumb rhythmbox
57 upgraded, 0 newly installed, 0 removed and 3 not upgraded.
Need to get 59.7MB/87.9MB of archives.
After unpacking 11.8MB of additional disk space will be used.
Do you want to continue? [Y/n]

Enter Y to upgrade the listed packages; otherwise, enter N. Packages that are not upgraded because they depend on packages that are not already installed are listed as kept back.

Use dist-upgrade to upgrade all packages, including packages that are dependent on packages that are not installed. This command also installs dependencies.

# apt-get dist-upgrade
Reading Package Lists... Done
Building Dependency Tree... Done
Calculating Upgrade... Done
The following packages will be upgraded
    gstreamer-plugins gthumb rhythmbox
The following NEW packages will be installed:
    Hermes flac libexif libid3tag
3 upgraded, 4 newly installed, 0 removed and 0 not upgraded.
Need to get 4510kB of archives.
After unpacking 6527kB of additional disk space will be used.
Do you want to continue? [Y/n]

Adding And Removing Individual Packages

The format of a command to install a specific software package and the packages it is dependent on is

```
apt-get install package
```

where `package` is the name of the package, such as `zsh`, and not the name of the `rpm`, which usually includes version and architecture information (for example, `zsh-1.2.i386.rpm`).

```
# apt-get install zsh
Reading Package Lists... Done
Building Dependency Tree... Done
The following NEW packages will be installed:
  zsh
0 upgraded, 1 newly installed, 0 removed and 0 not upgraded.
Need to get 1435kB of archives.
After unpacking 2831kB of additional disk space will be used.
Get:1 http://ayo.freshrpms.net fedora/linux/3/i386/core zsh 4.2.0-3 [1435kB]
Fetched 1435kB in 21s (66.0kB/s)
Committing changes...
Preparing... ........................................................... [100%]
  1:zsh .............................................................. [100%]
Done.
```

Remove a package the same way you install a package, substituting `remove` for `install`:

```
# apt-get remove zsh
Reading Package Lists... Done
Building Dependency Tree... Done
```
The following packages will be REMOVED:

   zsh

0 upgraded, 0 newly installed, 1 removed and 0 not upgraded.

Need to get 0B of archives.

After unpacking 2831kB disk space will be freed.

Do you want to continue? [Y/n] y

Committing changes...

Preparing...                          ########################################### [100%]

Done.

To ensure that you can later reinstall a package with the same configuration, the **apt-get remove** command does not remove configuration files from the `/etc` directory hierarchy. Although it is not recommended, you can use the `purge` option to remove all of these files, including configuration files. Alternatively, you can move these files to an archive so you can restore them later if necessary.

apt.conf: Configuring Apt

The `/etc/apt/apt.conf` file contains Apt configuration information and is split into three sections: **APT**, which contains global settings for the Apt tools; Acquire, which describes settings related to the package-fetching mechanism; and **RPM**, which contains `rpm`-specific settings. In this file semicolons (;) separate statements and double forward slashes (//) introduce comments.

**APT section**

The **APT** section is shown following:

```bash
$ cat /etc/apt/apt.conf

APT {
    Clean-Installed "false";
    Get {
        Assume-Yes "false";
        Download-Only "false";
        Show-Upgraded "true";
    }
}
```
Fix-Broken "false";
Ignore-Missing "false";
Compile "false";
}
}
...

When you set Clean-Installed to TRUE, Apt removes packages that are no longer in the repository.

The options in the Get subsection listed here apply to the apt-get utility (the apt-get utility has command line arguments with the same names as these options):

- **Assume-Yes** TRUE runs apt-get in batch mode, automatically answering YES whenever it would otherwise prompt you for input.
- **Download-Only** TRUE retrieves packages from the repository but does not install them. FALSE retrieves and installs the packages.
- **Show-Upgraded** TRUE displays a list of upgraded packages.
- **Fix-Broken** TRUE attempts to fix dependency tree problems with varying degrees of success. FALSE quits if it finds a dependency tree problem.
- **Ignore-Missing** TRUE holds back missing or corrupt packages and continues to install other packages. FALSE aborts the entire install or upgrade upon finding a missing or corrupt package.
- **Compile** TRUE compiles and installs source rpm (SRPM) packages that you ask apt-get to retrieve. FALSE downloads these files without compiling or installing them.

**Acquire section** The Acquire section controls options related to fetching packages.

```
$ cat /etc/apt/apt.conf
...
Acquire {
Retries "0";
Http {
Proxy ""; // http://user:pass@host:port/
}
};
...
```

The **Retries** option specifies the number of times Apt attempts to fetch a package when an attempt fails. The **Http Proxy** setting specifies the proxy to use when fetching packages using HTTP. The argument to this option is blank
by default, indicating that Apt should not use a proxy. An example proxy is shown as a comment.

**RPM section**

Following is the **RPM** section of **apt.conf**:

```
$ cat /etc/apt/apt.conf
...
RPM {

    Ignore { };
    Hold { };
    Allow-Duplicated { "^kernel$"; "^kernel-"; "^kmodule-"; "^gpg-pukey$" }

    Options { };
    Install-Options "";
    Erase-Options "";
    Source {
        Build-Command "rpmbuild --rebuild";
    }
}
```

The **Ignore** and **Hold** options perform similar functions and contain lists of packages that Apt ignores or holds (does not upgrade). They are usually blank.

The **Allow-Duplicated** section lists packages that can have more than one version on the system at one time. In general you do not want to have multiple versions of the same package on a system. The kernel is an exception: It is good practice to leave the old kernel installed when you install a new kernel in case you are unable to boot the new one.

The **Options** section contains options that are passed to **rpm**. The **Install-Options** and **Erase-Options** sections contain options that are passed to **rpm** whenever it is used to install or erase a package.

The **Source Build-Command** option specifies the command that Apt uses to build a source **rpm** file.
**BitTorrent**

The BitTorrent protocol implements a hybrid client/server and P2P (page 891) file transfer mechanism. BitTorrent efficiently distributes large amounts of static data, such as installation ISO images. It can replace protocols such as anonymous FTP, where client authentication is not required. Each BitTorrent client that downloads a file provides additional bandwidth for uploading the file, reducing the load on the initial source. In general BitTorrent downloads proceed more rapidly than FTP downloads.

Unlike protocols such as FTP, BitTorrent groups multiple files into a single package called a **torrent**. For example, you can typically download several installation ISO images as a single torrent.

Like other P2P systems, BitTorrent does not use a dedicated server. Instead, the functions of a server are performed by the tracker, peers, and seeds. The **tracker** allows clients to communicate with each other. A client called a **peer** when it has downloaded part of the torrent and a **seed** once it has downloaded the entire torrent acts as an additional source for the torrent. As with a P2P network, each peer and seed that downloads a torrent uploads to other clients the sections of the torrent it already has. There is nothing special about a seed: It can be removed at any time once the torrent is available for download from other seeds.

The BitTorrent program is available from [www.bittorrent.com](http://www.bittorrent.com). After you download and install BitTorrent, the first step in downloading a torrent using BitTorrent is to locate or acquire a **.torrent** file. A **.torrent** file contains the information about the torrent, such as its size and the location of the tracker. You can use a **.torrent** file using its **URI** ([908](#)) or you can acquire it via the Web, an email attachment, or other means. The next step is for the BitTorrent client to connect to the tracker to learn the locations of other clients that it can download the torrent from.

Once you have downloaded a torrent, it is good manners to allow BitTorrent to continue to run so other clients can upload at least as much information as you have downloaded.

**Prerequisites**

If no BitTorrent **rpm** file exists for your version of Linux, use an **rpm** file for a similar version. Because BitTorrent is written in Python and runs on any platform with a Python interpreter, it is not dependent on system architecture. The **noarch** in the name of the **rpm** file stands for no architecture.

To run, BitTorrent requires Python, which is installed as **/usr/bin/python** on many systems. Python is available in the **python** **rpm** package.

**How Bittorrent Works**

The official BitTorrent distribution includes three client applications. You can use any of these applications to download BitTorrent files:

- **btdownloadheadless.py** A text-based client that writes the status to standard output. Good for unattended downloads where the output is redirected to a file.

- **btdownloadcurses.py** A text-based client that provides a pseudographical interface. Good for attended downloads to machines not running a GUI.

- **btdownloadgui.py** A graphical client.

In addition to the official clients, several other clients provide extra features. Some of these clients are available on [sourceforge.net](http://sourceforge.net).
Using BitTorrent

To use BitTorrent, first locate the `.torrent` file for the torrent you want to download. You can copy the `.torrent` file to the working directory (the first format shown below) or specify it with a `--url` option (second format). The simplest BitTorrent command lines have the following formats:

```
$ btdownloadheadless.py --responsefile tfile.torrent [--saveas savefile]
```

or

```
$ btdownloadheadless.py --url http://domain/tfile.torrent [--saveas savefile]
```

where `tfile.torrent` is the name of, or `http://domain/tfile.torrent` is the URI for, the `.torrent` file, and `savefile` is the location to save the torrent in. In the case of torrents containing a single file, the file is saved as `savefile`. For torrents containing multiple files, the files are saved in a directory named `savefile`. If you omit the `--saveas` argument, the files are saved in the name specified in the `.torrent` file. Because each of the `btdownload*` applications takes the same arguments, the preceding formats work for all three applications.

The next example shows how to download Fedora Core 3 ISO images. These large files take considerable time to download. To start the download, give the following command. Because the command line is long, it is broken by a backslash (`\`). Make sure no character follows the backslash, or else the backslash will not quote the following RETURN and the command will fail. (The shell supplies the `>` on the second line.)

```
$ btdownloadheadless.py --max_upload_rate 8 \ 
> --url http://torrent.dulug.duke.edu/heidelberg-binary-i386.torrent
```

The preceding command uses a URI to specify a `.torrent` file and saves the downloaded files in a directory named `heidelberg` (the name of the Fedora release) as specified by the `.torrent` file.

The `--max_upload_rate 8` option prevents BitTorrent from using more than 8 kilobytes per second of upstream bandwidth. BitTorrent usually gives higher download rates to clients that upload more, so feel free to increase this value if you have spare bandwidth. You need to leave enough free upstream bandwidth for the acknowledgment packets from your download to get through or your download will be very slow. By default the client uploads to a maximum of seven other clients at once. You can change this value by specifying the `--max_uploads` argument, followed by the maximum number of concurrent uploads you wish to permit. The default value of 7 is usually appropriate for typical broadband connections.

After you give the preceding command, the screen quickly fills with output that looks similar to the following:

```
saving: heidelberg-binary-i386
percent done: 0.0
```
download to: /home/max/heidelberg-binary-i386

upload rate: 0.0 KB/s

share rating: 0.000 (0.0 MB up / 1.2 MB down)

seed status: 30 seen now, plus 1 distributed copies (2:81.5%, 3:23.0%, 4:2.1%)

peer status: 5 seen now

The file size is that of all the files you are downloading: four ISO images and several smaller files. To abort the download, press CONTROL-C. The download will automatically resume from where it left off when you download the same torrent to the same location again.

Use the following command to perform the same download as in the previous example, this time throttling the rate and number of uploads to values sensible for modem users. (The shell supplies the > on the second line, you do not enter it.)

$ btdownloads.py --max_upload_rate 3 --max_uploads 2 \
> --url http://torrent.dulug.duke.edu/heidelberg-binary-i386.torrent

The preceding command displays output similar to the following:

```
----------------------------------------------------------------------------
--
| file: heidelberg-binary-i386 |
| size: 2,467,681,047 (2 GiB) |
| dest: /home/max/heidelberg-binary-i386 |
| progress: |
| status: finishing in 6:40:42 (1.0%) |
| dl speed: 285.6 KB/s |
| ul speed: 2.6 KB/s
```
Glossary

All entries marked with FOLDOC are based on definitions in the Free Online Dictionary of Computing (www.foldoc.org), Denis Howe, editor. Used with permission.

10.0.0.0

See [private address space]

172.16.0.0

See [private address space]

192.168.0.0

See [private address space]

802.11

A family of specifications developed by IEEE for wireless LAN technology, including 802.11 (112 megabits per second), 802.11a (54 megabits per second), 802.11b (11 megabits per second), and 802.11g (20+ megabits per second).

absolute pathname

A pathname that starts with the root directory (/). An absolute pathname locates a file without regard to the working directory.

access

In computer jargon, a verb meaning to use, read from, or write to. To access a file means to read from or write to the file.

Access Control List

See [ACL]

access permission

Permission to read from, write to, or execute a file. If you have write access permission to a file, you can write to the file. Also access privilege.
ACL

Access Control List. A system that performs a function similar to file permissions but with much finer-grain control.

active window

On a desktop, the window that receives the characters you type on the keyboard. Same as focus, desktop (page 875).

address mask

See [subnet mask]

alias

A mechanism of a shell that enables you to define new commands.

alphanumeric character

One of the characters, either uppercase or lowercase, from A to Z and 0 to 9, inclusive.

ambiguous file reference

A reference to a file that does not necessarily specify any one file but can be used to specify a group of files. The shell expands an ambiguous file reference into a list of filenames. Special characters represent single characters (?), strings of zero or more characters (*), and character classes ([ ] ) within ambiguous file references. An ambiguous file reference is a type of regular expression (page 897).

angle bracket

A left angle bracket (<) and a right angle bracket (>). The shell uses < to redirect a command's standard input to come from a file and > to redirect the standard output. The shell uses the characters << to signify the start of a Here document and >> to append output to a file.

animate

When referring to a window action, means that the action is slowed down so the user can view it. For example, when you minimize a window, it can disappear all at once (not animated) or it can slowly telescope into the panel so you can get a visual feel for what is happening (animated).
anti-aliasing

Adding gray pixels at the edge of a diagonal line to get rid of the jagged appearance and thereby make the line look smoother. Anti-aliasing sometimes makes type on a screen look better and sometimes worse; it works best on small and large fonts and is less effective on fonts from 8 to 15 points.

See also [subpixel hinting]

API

Application Program Interface. The interface (calling conventions) by which an application program accesses an operating system and other services. An API is defined at the source code level and provides a level of abstraction between the application and the kernel (or other privileged utilities) to ensure the portability of the code. FOLDOC

append

To add something to the end of something else. To append text to a file means to add the text to the end of the file. The shell uses `>>` to append a command's output to a file.

applet

A small program that runs within a larger program. Examples are Java applets that run in a browser and panel applets that run from a desktop panel.

argument

A number, letter, filename, or another string that gives some information to a command and is passed to the command when it is called. A command line argument is anything on a command line following the command name that is passed to the command. An option is a kind of argument.

arithmetic expression

A group of numbers, operators, and parentheses that can be evaluated. When you evaluate an arithmetic expression, you end up with a number. The Bourne Again Shell uses the `expr` command to evaluate arithmetic expressions; the TC Shell uses `@`; and the Z Shell uses `let`.

array

An arrangement of elements (numbers or strings of characters) in one or more dimensions. The TC and Z
Shells and \texttt{gawk} can store and process arrays.

**ASCII**

American Standard Code for Information Interchange. A code that uses seven bits to represent both graphic (letters, numbers, and punctuation) and control characters. You can represent textual information, including program source code and English text, in ASCII code. Because ASCII is a standard, it is frequently used when exchanging information between computers. See the file /\texttt{usr/pub/ascii} or give the command \texttt{man ascii} to see a list of ASCII codes.

Extensions of the ASCII character set use eight bits. The seven-bit set is common; the eight-bit extensions are still coming into popular use. The eighth bit is sometimes referred to as the metabit.

**ASCII terminal**

A text-based terminal. Contrast with \textit{graphical display} (page 877).

**ASP**

Application Service Provider. A company that provides applications over the Internet.

**asynchronous event**

An event that does not occur regularly or synchronously with another event. Linux system signals are asynchronous; they can occur at any time because they can be initiated by any number of nonregular events.

**attachment**

A file that is attached to, but is not part of, a piece of email. Attachments are frequently opened by programs (including your Internet browser) that are called by your mail program so you may not be aware that they are not an integral part of an email message.

**authentication**

The verification of the identity of a person or process. In a communication system, authentication verifies that a message comes from its stated source. Methods of authentication on a Linux system include the \texttt{/etc/passwd} and \texttt{/etc/shadow} files, LDAP, Kerberos 5, and SMB authentication.

**automatic mounting**
A way of demand mounting directories from remote hosts without having them hard configured into 
/etc/fstab. Also called automounting.

avoided

An object, such as a panel, that should not normally be covered by another object, such as a window.

back door

A security hole deliberately left in place by the designers or maintainers of a system. The motivation for creating such holes is not always sinister; some operating systems, for example, come out of the box with privileged accounts intended for use by field service technicians or the vendor's maintenance programmers.

Ken Thompson's 1983 Turing Award lecture to the ACM revealed the existence, in early UNIX versions, of a back door that may be the most fiendishly clever security hack of all time. The C compiler contained code that would recognize when the login command was being recompiled and would insert some code recognizing a password chosen by Thompson, giving him entry to the system whether or not an account had been created for him.

Normally such a back door could be removed by removing it from the source code for the compiler and recompiling the compiler. But to recompile the compiler, you have to use the compiler, so Thompson arranged that the compiler would recognize when it was compiling a version of itself. It would insert into the recompiled compiler the code to allow Thompson entry, and, of course, the code to recognize itself and do the whole thing again the next time around. Having done this once, he was then able to recompile the compiler from the original sources; the hack perpetuated itself invisibly, leaving the back door in place and active but with no trace in the sources.

Sometimes called a wormhole. Also trap door.  

background process

A process that is not run in the foreground. Also called a detached process, a background process is initiated by a command line that ends with an ampersand (&). You do not have to wait for a background process to run to completion before giving the shell additional commands. If you have job control, you can move background processes to the foreground, and vice versa.

basename

The name of a file that, in contrast with a pathname, does not mention any of the directories containing the file (and therefore does not contain any slashes [/]). For example, hosts is the basename of /etc/hosts.

baud
The maximum information-carrying capacity of a communication channel in symbols (state transitions or level transitions) per second. It coincides with bits per second only for two-level modulation with no framing or stop bits. A symbol is a unique state of the communication channel, distinguishable by the receiver from all other possible states. For example, it may be one of two voltage levels on a wire for a direct digital connection, or it might be the phase or frequency of a carrier.

Baud is often mistakenly used as a synonym for bits per second.

**baud rate**

Transmission speed. Usually used to measure terminal or modem speed. Common baud rates range from 110 to 38,400 baud.

See also [baud]

**Berkeley UNIX**

One of the two major versions of the UNIX operating system. Berkeley UNIX was developed at the University of California at Berkeley by the Computer Systems Research Group and is often referred to as BSD (Berkeley Software Distribution).

**BIND**

Berkeley Internet Name Domain. An implementation of a DNS server developed and distributed by the University of California at Berkeley.

**BIOS**

Basic Input/Output System. On PCs, EEPROM-based system software that provides the lowest-level interface to peripheral devices and controls the first stage of the bootstrap process, which loads the operating system. The BIOS can be stored in different types of memory. The memory must be nonvolatile so that it remembers the system's settings even when the system is turned off. Also BIOS ROM.

**bit**

The smallest piece of information a computer can handle. A bit is a binary digit: either 1 or 0 (on or off).

**bit depth**

Same as color depth (page 868).
bit-mapped display

A graphical display device in which each pixel on the screen is controlled by an underlying representation of zeros and ones.

blank character

Either a SPACE or a TAB character, also called whitespace (page 909). In some contexts, NEWLINEs are considered blank characters.

block

A section of a disk or tape (usually 1,024 bytes long but shorter or longer on some systems) that is written at one time.

block device

A disk or tape drive. A block device stores information in blocks of characters. A block device is represented by a block device (block special) file. Contrast with character device (page 866).

block number

Disk and tape blocks are numbered so that Linux can keep track of the data on the device.

blocking factor

The number of logical blocks that make up a physical block on a tape or disk. When you write 1K logical blocks to a tape with a physical block size of 30K, the blocking factor is 30.

boot

See [bootstrap]

boot loader

A very small program that takes its place in the bootstrap process that brings a computer from off or reset to a fully functional state.

bootstrap
Derived from "Pull oneself up by one's own bootstraps," the incremental process of loading an operating system kernel into memory and starting it running without any outside assistance. Frequently shortened to *boot*.

**Bourne Again Shell**

*bash*. GNU's command interpreter for UNIX, *bash* is a POSIX-compliant shell with full Bourne Shell syntax and some C Shell commands built in. The Bourne Again Shell supports *emacs*-style command line editing, job control, functions, and online help.  

**Bourne Shell**

*sh*. This UNIX command processor was developed by Steve Bourne at AT&T Bell Laboratories.

**brace**

A left brace ( { ) and a right brace ( } ). Braces have special meanings to the shell.

**bracket**

*A square bracket* (page 902) or an *angle bracket* (page 860).

**branch**

In a tree structure, a branch connects nodes, leaves, and the root. The Linux filesystem hierarchy is often conceptualized as an upside-down tree. The branches connect files and directories. In a source code control system, such as SCCS or RCS, a branch occurs when a revision is made to a file and is not included in subsequent revisions to the file.

**bridge**

Typically a two-port device originally used for extending networks at layer 2 (data link) of the Internet Protocol model.

**broadcast**

A transmission to multiple, unspecified recipients. On Ethernet a broadcast packet is a special type of multicast packet that has a special address indicating that all devices that receive it should process it. Broadcast traffic exists at several layers of the network stack, including Ethernet and IP. Broadcast traffic has one source but indeterminate destinations (all hosts on the local network).
**broadcast address**

The last address on a subnet (usually 255), reserved as shorthand to mean all hosts.

**broadcast network**

A type of network, such as Ethernet, in which any system can transmit information at any time, and all systems receive every message.

**BSD**

See [Berkeley UNIX]

**buffer**

An area of memory that stores data until it can be used. When you write information to a file on a disk, Linux stores the information in a disk buffer until there is enough to write to the disk or until the disk is ready to receive the information.

**bug**

An unwanted and unintended program property, especially one that causes the program to malfunction. [FOLDOC]

**builtin (command)**

A command that is built into a shell. Each of the three major shells—the Bourne Again, TC, and Z Shells—has its own set of builtins. Refer to "Builtins" on page 132.

**byte**

A component in the machine data hierarchy, usually larger than a bit and smaller than a word; now most often eight bits and the smallest addressable unit of storage. A byte typically holds one character. [FOLDOC]

**C programming language**

A modern systems language that has high-level features for efficient, modular programming as well as lower-level features that make it suitable for use as a systems programming language. It is machine
independent so that carefully written C programs can be easily transported to run on different machines. Most of the Linux operating system is written in C, and Linux provides an ideal environment for programming in C.

C Shell

csh. The C Shell command processor was developed by Bill Joy for BSD UNIX. It was named for the C programming language because its programming constructs are similar to those of C.

See also [shell]

cable modem

A type of modem that allows you to access the Internet by using your cable television connection.

cache

Holding recently accessed data, a small, fast memory designed to speed up subsequent access to the same data. Most often applied to processor-memory access but also used for a local copy of data accessible over a network, from a hard disk, and so on. FOLDOC

calling environment

A list of variables and their values that is made available to a called program. Refer to "Executing a Command" on page 294.

cascading stylesheet

See [CSS]

cascading windows

An arrangement of windows such that they overlap, generally with at least part of the title bar visible. Opposite of tiled windows (page 906).

case sensitive

Able to distinguish between uppercase and lowercase characters. Unless you set the ignorecase parameter, vim performs case-sensitive searches. The grep utility performs case-sensitive searches unless you use the -i option.
catenate

To join sequentially, or end to end. The Linux cat utility catenates files: It displays them one after the other. Also concatenate.

chain loading

The technique used by a boot loader to load unsupported operating systems. Used for loading such operating systems as DOS or Windows, it works by loading another boot loader.

character-based

A program, utility, or interface that works only with ASCII (page 861) characters. This set of characters includes some simple graphics, such as lines and corners, and can display colored characters. It cannot display true graphics. Contrast with GUI (page 877).

character-based terminal

A terminal that displays only characters and very limited graphics.

See also [character-based]

character class

In a regular expression, a group of characters that defines which characters can occupy a single character position. A character-class definition is usually surrounded by square brackets. The character class defined by [abcr] represents a character position that can be occupied by a, b, c, or r. Also list operator.

character device

A terminal, printer, or modem. A character device stores or displays characters one at a time. A character device is represented by a character device (character special) file. Contrast with block device (page 864).

checksum

A computed value that depends on the contents of a block of data and is transmitted or stored along with the data to detect corruption of the data. The receiving system recomputes the checksum based on the received data and compares this value with the one sent with the data. If the two values are the same, the receiver has some confidence that the data was received correctly.
The checksum may be 8, 16, or 32 bits, or some other size. It is computed by summing the bytes or words of the data block, ignoring overflow. The checksum may be negated so that the total of the data words plus the checksum is zero.

Internet packets use a 32-bit checksum.  

**child process**

A process that is created by another process, the parent process. Every process is a child process except for the first process, which is started when Linux begins execution. When you run a command from the shell, the shell spawns a child process to run the command.

See also [process]

**CIDR**

Classless Inter-Domain Routing. A scheme that allocates blocks of Internet addresses in a way that allows summarization into a smaller number of routing table entries. A CIDR block is a block of Internet addresses assigned to an ISP by the Internic.  

**CIFS**

Common Internet File System. An Internet filesystem protocol based on SMB (page 901). CIFS runs on top of TCP/IP, uses DNS, and is optimized to support slower dial-up Internet connections. SMB and CIFS are used interchangeably.  

**CIPE**

Crypto IP Encapsulation (page 874). This protocol tunnels IP packets within encrypted UDP packets, is lightweight and simple, and works over dynamic addresses, NAT (page 889), and SOCKS proxies (page 895).

**cipher (cypher)**

A cryptographic system that uses a key to transpose/substitute characters within a message, the key itself, or the message.

**ciphertext**

Text that is encrypted. Contrast with plaintext (page 893).
Classless Inter-Domain Routing

See [CIDR]

cleartext

Text that is not encrypted; also plaintext. Contrast with ciphertext.

CLI

Command line interface.

See also [character-based]

client

A computer or program that requests one or more services from a server.

CODEC

Coder/decoder or compressor/decompressor. A hardware and/or software technology that codes and decodes data. MPEG is a popular CODEC for computer video.

color depth

The number of bits used to generate a pixel—usually 8, 16, 24, or 32. The color depth is directly related to the number of colors that can be generated. The number of colors that can be generated is $2^{\text{color-depth}}$. Thus that a 24-bit video adapter can generate about 16.7 million colors.

color quality

See [color depth]

combo box

A combination of a list and text entry box. A user can either select an option from a provided list or enter his own option.

command
What you give the shell in response to a prompt. When you give the shell a command, it executes a utility, another program, a builtin command, or a shell script. Utilities are often referred to as commands. When you are using an interactive utility, such as `vim` or `mail`, you use commands that are appropriate to that utility.

**command line**

A line containing instructions and arguments that executes a command. This term usually refers to a line that you enter in response to a shell prompt on a character-based terminal or terminal emulator.

**command substitution**

Replacing a command with its output. The shells perform command substitution when you enclose a command between `$(` and `)` or between a pair of back ticks (`'`), also called grave accent marks.

**component architecture**

A notion in object-oriented programming where "components" of a program are completely generic. Instead of having a specialized set of methods and fields, they have generic methods through which the component can advertise the functionality it supports to the system into which it is loaded. This strategy enables completely dynamic loading of objects. JavaBeans is an example of a component architecture. FOLDOC

**concatenate**

See [catenate]

**condition code**

See [exit status]

**connection-oriented protocol**

A type of transport layer data communication service that allows a host to send data in a continuous stream to another host. The transport service guarantees that all data will be delivered to the other end in the same order as sent and without duplication. Communication proceeds through three well-defined phases: connection establishment, data transfer, and connection release. The most common example is TCP (page 905).

Also called connection-based protocol and stream-oriented protocol. Contrast with connectionless protocol and datagram (page 870). FOLDOC

**connectionless protocol**
The data communication method in which communication occurs between hosts with no previous setup. Packets sent between two hosts may take different routes. There is no guarantee that packets will arrive as transmitted or even that they will arrive at the destination at all. UDP (page 907) is a connectionless protocol. Also called packet switching. Contrast with circuit switching and connection-oriented protocol.

**console**

See [system console]

**console terminal**

See [system console]

**control character**

A character that is not a graphic character, such as a letter, number, or punctuation mark. Such characters are called control characters because they frequently act to control a peripheral device. RETURN and FORMFEED are control characters that control a terminal or printer.

The word CONTROL is shown in this book in THISFONT because it is a key that appears on most terminal keyboards. Control characters are represented by ASCII codes less than 32 (decimal).

See also [nonprinting character]

**control structure**

A statement used to change the order of execution of commands in a shell script or other program. Each shell provides control structures (for example, **If** and **While**) as well as other commands that alter the order of execution (for example, **exec**). Also control flow commands.

**cookie**

Data stored on a client system by a server. The client system browser sends the cookie back to the server each time it accesses that server. For example, a catalog shopping service may store a cookie on your system when you place your first order. When you return to the site, it knows who you are and can supply your name and address for subsequent orders. You may consider cookies to be an invasion of privacy.

**CPU**

Central processing unit. The part of a computer that controls all the other parts. The CPU includes the control unit and the arithmetic and logic unit (ALU). The control unit fetches instructions from memory and decodes them to produce signals that control the other parts of the computer. These signals can cause data to
be transferred between memory and ALU or peripherals to perform input or output. A CPU that is housed on a single chip is called a microprocessor. Also processor and central processor.

**cracker**

An individual who attempts to gain unauthorized access to a computer system. These individuals are often malicious and have many means at their disposal for breaking into a system. Contrast with hacker (page 877). 

**crash**

The system suddenly and unexpectedly stops or fails. Derived from the action of the hard disk heads on the surface of the disk when the air gap between the two collapses.

**cryptography**

The practice and study of encryption and decryption—encoding data so that only a specific individual or machine can decode it. A system for encrypting and decrypting data is a cryptosystem. Such systems usually rely on an algorithm for combining the original data (plaintext) with one or more keys—numbers or strings of characters known only to the sender and/or recipient. The resulting output is called ciphertext (page 867).

The security of a cryptosystem usually depends on the secrecy of keys rather than on the supposed secrecy of an algorithm. Because a strong cryptosystem has a large range of keys, it is not possible to try all of them. Ciphertext appears random to standard statistical tests and resists known methods for breaking codes.

**.cshrc file**

In your home directory, a file that the TC Shell executes each time you invoke a new TC Shell. You can use this file to establish variables and aliases.

**CSS**

Cascading stylesheet. Describes how documents are presented on screen and in print. Attaching a stylesheet to a structured document can affect the way it looks without adding new HTML (or other) tags and without giving up device independence. Also stylesheet.

**current (process, line, character, directory, event, and so on)**

The item that is immediately available, working, or being used. The current process controls the program you are running, the current line or character is the one the cursor is on, and the current directory is the working directory.
cursor

A small lighted rectangle, underscore, or vertical bar that appears on the terminal screen and indicates where the next character will appear. Differs from the mouse pointer (page 888).

daemon

A program that is not invoked explicitly but lies dormant, waiting for some condition(s) to occur. The perpetrator of the condition need not be aware that a daemon is lurking (although often a program will commit an action only because it knows that it will implicitly invoke a daemon). From the mythological meaning, later rationalized as the acronym Disk And Execution MONitor.  

FOLDOC

data structure

A particular format for storing, organizing, working with, and retrieving data. Frequently, data structures are designed to work with specific algorithms that facilitate these tasks. Common data structures include trees, files, records, tables, arrays, and so on.

datagram

A self-contained, independent entity of data carrying sufficient information to be routed from the source to the destination computer without reliance on earlier exchanges between this source and destination computer and the transporting network. UDP (page 907) uses datagrams; IP (page 882) uses packets (page 892). Packets are indivisible at the network layer; datagrams are not.  

FOLDOC  

See also [frame]

dataless

A computer, usually a workstation, that uses a local disk to boot a copy of the operating system and access system files but does not use a local disk to store user files.

dbm

A standard, simple database manager. Implemented as gdbm (GNU database manager), it uses hashes to speed searching. The most common versions of the dbm database are dbm, ndbm, and gdbm.

DDoS attack
Distributed denial of service attack. A DoS attack (page 873) from many systems that do not belong to the perpetrator of the attack.

**debug**

To correct a program by removing its bugs (that is, errors).

**default**

Something that is selected without being explicitly specified. For example, when used without an argument, `ls` displays a list of the files in the working directory by default.

**delta**

A set of changes made to a file that has been encoded by the Source Code Control System (SCCS).

**denial of service**

See [DoS attack]

**dereference**

When speaking of symbolic links, follow the link rather than working with the reference to the link. For example, the `-L` or `--dereference` option causes `ls` to list the entry that a symbolic link points to rather than the symbolic link (the reference) itself.

**desktop**

A collection of windows, toolbars, icons, and buttons, some or all of which appear on your display. A desktop comprises one or more workspaces (page 910).

**desktop manager**

An icon- and menu-based user interface to system services that allows you to run applications and use the filesystem without using the system’s command line interface.

**detached process**
See [background process]

**device**

A disk drive, printer, terminal, plotter, or other input/output unit that can be attached to the computer.

**device driver**

Part of the Linux kernel that controls a device, such as a terminal, disk drive, or printer.

**device file**

A file that represents a device. Also *special file*.

**device filename**

The pathname of a device file. All Linux systems have two kinds of device files: block and character device files. Linux also has FIFOs (named pipes) and sockets. Device files are traditionally located in the `/dev` directory.

**device number**

See also [major device number]
See also [minor device number]

**DHCP**

Dynamic Host Configuration Protocol. A protocol that dynamically allocates IP addresses to computers on a LAN.  

**directory**

Short for *directory file*. A file that contains a list of other files.

**directory hierarchy**

A directory, called the root of the directory hierarchy, and all the directory and ordinary files below it (its children).
directory service

A structured repository of information on people and resources within an organization, facilitating management and communication. [FOLDOC]

disk partition

See [partition]

diskless

A computer, usually a workstation, that has no disk and must contact another computer (a server) to boot a copy of the operating system and access the necessary system files.

distributed computing

A style of computing in which tasks or services are performed by a network of cooperating systems, some of which may be specialized.

DMZ

Demilitarized zone. A host or small network that is a neutral zone between a LAN and the Internet. It can serve Web pages and other data to the Internet and allow local systems access to the Internet while preventing LAN access to unauthorized Internet users. Even if a DMZ is compromised, it holds no data that is private and none that cannot be easily reproduced.

DNS

Domain Name Service. A distributed service that manages the correspondence of full hostnames (those that include a domain name) to IP addresses and other system characteristics.

DNS domain name

See [domain name]

document object model

See [DOM]

DOM
Document Object Model. A platform-/language-independent interface that enables a program to update the content, structure, and style of a document dynamically. The changes can then be made part of the displayed document. Go to www.w3.org/DOM for more information.

**domain name**

A name associated with an organization, or part of an organization, to help identify systems uniquely. Technically, the part of the *FQDN* (page 876) to the right of the leftmost period. Domain names are assigned hierarchically. The domain berkeley.edu refers to the University of California at Berkeley, for example; it is part of the top-level edu (education) domain. Also DNS domain name. Different than *NIS domain name* (page 890).

**Domain Name Service**

See [DNS]

**door**

An evolving filesystem-based *RPC* (page 899) mechanism.

**DoS attack**

Denial of service attack. An attack that attempts to make the target host or network unusable by flooding it with spurious traffic.

**DPMS**

Display Power Management Signaling. A standard that can extend the life of CRT monitors and conserve energy. DPMS supports four modes for a monitor: Normal, Standby (power supply on, monitor ready to come to display images almost instantly), Suspend (power supply off, monitor takes up to ten seconds to display an image), and Off.

**drag**

To move an icon from one position or application to another, usually in the context of a window manager. The motion part of drag-and-drop.

**druid**

In role-playing games, a character that represents a magical user. Red Hat uses the term *druid* at the ends of names of programs that guide you through a task-driven chain of steps. Other operating systems call these
types of programs *wizards*.

**DSA**

Digital Signature Algorithm. A public key cipher used to generate digital signatures.

**DSL**

Digital Subscriber Line/Loop. Provides high-speed digital communication over a specialized, conditioned telephone line.

See also [xDSL]

**Dynamic Host Configuration Protocol**

See [DHCP]

**editor**

A utility, such as *vim* or *emacs*, that creates and modifies text files.

**EEPROM**

Electrically erasable, programmable, readonly memory. A *PROM* (page 895) that can be written to.

**effective user ID**

The user ID that a process appears to have; usually the same as the user ID. For example, while you are running a setuid program, the effective user ID of the process running the program is that of the owner of the program.

**element**

One thing; usually a basic part of a group of things. An element of a numeric array is one of the numbers stored in the array.

**emoticon**
See [smiley]

encapsulation

See [tunneling]

evironment

See [calling environment]

EOF

End of file.

EPROM

Erasable, programmable, readonly memory. A PROM (page 895) that can be written to by applying a higher than normal voltage.

escape

See [quote]

Ethernet

A type of LAN (page 884) capable of transfer rates as high as 1,000 megabits per second.

event

An occurrence, or happening, of significance to a task or program—for example, the completion of an asynchronous input/output operation, such as a keypress or mouse click.  

exabyte

$2^{60}$ bytes or about $10^{18}$ bytes.

See also [large number]

exit status

The status returned by a process; either successful (usually 0) or unsuccessful (usually 1).
exploit

A security hole or an instance of taking advantage of a security hole.  \[\text{FOLDOC}\]

expression

See also \[\text{logical expression}\]
See also \[\text{arithmetic expression}\]

extranet

A network extension for a subset of users (such as students at a particular school or engineers working for the same company). An extranet limits access to private information even though it travels on the public Internet.

failsafe session

A session that allows you to log in on a minimal desktop in case your standard login does not work well enough to allow you to log in to fix a login problem.

FDDI

Fiber Distributed Data Interface. A type of LAN (page 884) designed to transport data at the rate of 100 million bits per second over fiberoptic cable.

file

A collection of related information referred to with a filename and frequently stored on a disk. Text files typically contain memos, reports, messages, program source code, lists, or manuscripts. Binary or executable files contain utilities or programs that you can run. Refer to "Directory and Ordin\[\text{ary Files}" on page 77.

filename

The name of a file. A filename refers to a file.

filename completion
Automatic completion of a filename after you specify a unique prefix.

**filename extension**

The part of a filename following a period.

**filename generation**

What occurs when the shell expands ambiguous file references.

See also [ambiguous file reference]

**filesystem**

A *data structure* (page 870) that usually resides on part of a disk. All Linux systems have a root filesystem, and most have at least a few other filesystems. Each filesystem is composed of some number of blocks, depending on the size of the disk partition that has been assigned to the filesystem. Each filesystem has a control block, named the superblock, that contains information about the filesystem. The other blocks in a filesystem are inodes, which contain control information about individual files, and data blocks, which contain the information in the files.

**filling**

A variant of maximizing in which window edges are pushed out as far as they can go without overlapping another window.

**filter**

A command that can take its input from standard input and send its output to standard output. A filter transforms the input stream of data and sends it to standard output. A pipe usually connects a filter's input to standard output of one command, and a second pipe connects the filter's output to standard input of another command. The `grep` and `sort` utilities are commonly used as filters.

**firewall**

A device for policy-based traffic management used to keep a network secure. A firewall can be implemented in a single router that filters out unwanted packets, or it can rely on a combination of routers, proxy servers, and other devices. Firewalls are widely used to give users access to the Internet in a secure fashion and to separate a company's public WWW server from its internal network. They are also employed to keep internal network segments more secure.

Recently the term has come to be defined more loosely to include a simple packet filter running on an
Recently the term has come to be defined more loosely to include a simple packet filter running on an endpoint machine.

See also [proxy server]

**focus, desktop**

On a desktop the window that is active. The window with the desktop focus receives the characters you type on the keyboard. Same as active window (page 860).

**footer**

The part of a format that goes at the bottom (or foot) of a page. Contrast with header (page 878).

**foreground process**

When you run a command in the foreground, the shell waits for the command to finish before giving you another prompt. You must wait for a foreground process to run to completion before you can give the shell another command. If you have job control, you can move background processes to the foreground, and vice versa. Contrast with background process (page 863).

See also [job control]

**fork**

To create a process. When one process creates another process, it forks a process. Also spawn.

**FQDN**

Fully qualified domain name. The full name of a system, consisting of its hostname and its domain name, including the top-level domain. Technically the name that gethostbyname(2) returns for the host named by gethostname(2). For example, speedy is a hostname and speedy.example.com is an FQDN. An FQDN is sufficient to determine a unique Internet address for a machine on the Internet.

See also [datagram]
See also [packet]
free list

In a filesystem, the list of blocks that are available for use. Information about the free list is kept in the superblock of the filesystem.

free space

The portion of a hard disk that is not within a partition. A new hard disk has no partitions and contains all free space.

full duplex

The ability to receive and transmit data simultaneously. A network switch (page 890) is typically a full-duplex device. Contrast with half-duplex (page 877).

fully qualified domain name

See [FQDN]

function

See [shell function]

gateway

A generic term for a computer or a special device connected to more than one dissimilar type of network to pass data between them. Unlike a router, a gateway often must convert the information into a different format before passing it on. The historical usage of gateway to designate a router is deprecated.

GCOS

See [GECOS]

GECOS

General Electric Comprehensive Operating System. For historical reasons, the user information field in the /etc/passwd file is called the GECOS field. Also GCOS.

giga-

In the binary system, the prefix giga- multiplies by \(2^{30}\) (i.e., 1,073,741,824). Gigabit and gigabyte are
In the binary system, the prefix *giga*- multiplies by \(2^{30}\) (i.e., 1,073,741,824). Gigabit and gigabyte are common uses of this prefix. Abbreviated as \(G\).

See also [large number]

glyph

A symbol that communicates a specific piece of information nonverbally. A *smiley* (page 901) is a glyph.

GMT

Greenwich Mean Time.

See also [UTC]

graphical display

A bitmapped monitor that can display graphical images. Contrast with *ASCII terminal* (page 861).

graphical user interface

See [GUI]

group (of users)

A collection of users. Groups are used as a basis for determining file access permissions. If you are not the owner of a file and you belong to the group the file is assigned to, you are subject to the group access permissions for the file. A user can simultaneously belong to several groups.

group (of windows)

A way to identify similar windows so they can be displayed and acted on similarly. Typically windows started by a given application belong to the same group.

group ID

A unique number that identifies a set of users. It is stored in the password and group databases (/etc/passwd and /etc/group files or their NIS equivalents). The group database associates group IDs with group names.

GUI
Graphical user interface. A GUI provides a way to interact with a computer system by choosing items from menus or manipulating pictures drawn on a display screen instead of by typing command lines. Under Linux, the X Window System provides a graphical display and mouse/keyboard input. GNOME and KDE are two popular desktop managers that run under X. Contrast with character-based (page 866).

**hacker**

A person who enjoys exploring the details of programmable systems and learning how to stretch their capabilities, as opposed to users, who prefer to learn only the minimum necessary. One who programs enthusiastically (even obsessively) or who enjoys programming rather than just theorizing about programming. Contrast with **cracker** (page 869).

**half-duplex**

A half-duplex device can only receive or transmit at a given moment; it cannot do both. A **hub** (page 880) is typically a half-duplex device. Contrast with **full duplex** (page 876).

**hard link**

A directory entry that contains the filename and inode number for a file. The inode number identifies the location of control information for the file on the disk, which in turn identifies the location of the file's contents on the disk. Every file has at least one hard link, which locates the file in a directory. When you remove the last hard link to a file, you can no longer access the file.

See also [link]
See also [symbolic link]

**hash**

A string that is generated from another string. When used for security, a hash can prove, almost to a certainty, that a message has not been tampered with during transmission: The sender generates a hash of a message, encrypts the message and hash, and sends the encrypted message and hash to the recipient. The recipient decrypts the message and hash, generates a second hash from the message, and compares the hash that the sender generated to the new hash. When they are the same, the message has probably not been tampered with. A hash can also be used to create an index called a hash table. Also **hash value**.

See also [one-way hash function]

**hash table**

An index created from hashes of the items to be indexed. The hash function makes it highly unlikely that two items will create the same hash. To look up an item in the index, create a hash of the item and search for the hash. Because the hash is typically shorter than the item, the search is more efficient.
header

When you are formatting a document, the header goes at the top, or head, of a page. In electronic mail the header identifies who sent the message, when it was sent, what the subject of the message is, and so forth.

Here document

A shell script that takes its input from the file that contains the script.

hesiod

The name server of project Athena. Hesiod is a name service library that is derived from BIND (page 863) and leverages a DNS infrastructure.

heterogeneous

Consisting of different parts. A heterogeneous network includes systems produced by different manufacturers and/or running different operating systems.

hexadecimal number

A base 16 number. Hexadecimal (or hex) numbers are composed of the hexadecimal digits 0–9 and A–F. See Table G-1.

**hidden file**

See [invisible file]

**hierarchy**

An organization with a few things, or thingone at the topand with several things below each other thing. An inverted tree structure. Examples in computing include a file tree where each directory may contain files or other directories, a hierarchical network, and a class hierarchy in object-oriented programming. [FOLDOC]

Refer to "The Hierarchical Filesystem" on page 76.

**history**

A shell mechanism that enables you to modify and reexecute recent commands.

**home directory**

The directory that is your working directory when you first log in. The pathname of this directory is stored in the HOME shell variable.
hover

To leave the mouse pointer stationary for a moment over an object. In many cases hovering displays a *tooltip* (page 906).

**HTML**

Hypertext Markup Language. A *hypertext* (page 880) document format used on the World Wide Web. Tags, which are embedded in the text, consist of a less than sign (<), a directive, zero or more parameters, and a greater than sign (>). Matched pairs of directives, such as `<TITLE>` and `</TITLE>`, delimit text that is to appear in a special place or style. For more information on HTML, go to www.htmlhelp.com/faq/html/all.html.

**HTTP**

**hub**

A multiport repeater. A hub rebroadcasts all packets it receives on all ports. This term is frequently used to refer to small hubs and switches, regardless of the device’s intelligence. It is a generic term for a layer 2 shared-media networking device. Today the term *hub* is sometimes used to refer to small intelligent devices, although that was not its original meaning. Contrast with *network switch* (page 890).

**hypertext**

A collection of documents/nodes containing (usually highlighted or underlined) cross-references or links, which, with the aid of an interactive browser program, allow the reader to move easily from one document to another. For more information on hypertext, go to www.htmlhelp.com/faq/html/all.html.

**Hypertext Markup Language**

See [HTML]

**Hypertext Transfer Protocol**

See [HTTP]
i/o device

Input/output device.

See also [device]

IANA

Internet Assigned Numbers Authority. A group that maintains a database of all permanent, registered system services (www.iana.org).

ICMP

Internet Control Message Protocol. A type of network packet that carries only messages, no data.

icon

In a GUI, a small picture representing a file, directory, action, program, and so on. When you click an icon, an action, such as opening a window and starting a program or displaying a directory or Web site, takes place. From miniature religious statues. FOLDOC

iconify

The process of changing a window into an icon. Contrast with restore (page 897).

ignored window

A state in which a window has no decoration and therefore no buttons or titlebar to control it with.

indentation

See [indention]

indention

The blank space between the margin and the beginning of a line that is set in from the margin.

inode
A data structure (page 870) that contains information about a file. An inode for a file contains the file's length, the times the file was last accessed and modified, the time the inode was last modified, owner and group IDs, access privileges, number of links, and pointers to the data blocks that contain the file itself. Each directory entry associates a filename with an inode. Although a single file may have several filenames (one for each link), it has only one inode.

input

Information that is fed to a program from a terminal or other file.

See also [standard input]

installation

A computer at a specific location. Some aspects of the Linux system are installation dependent. Also site.

interactive

A program that allows ongoing dialog with the user. When you give commands in response to shell prompts, you are using the shell interactively. Also, when you give commands to utilities, such as vim and mail, you are using the utilities interactively.

interface

The meeting point of two subsystems. When two programs work together, their interface includes every aspect of either program that the other deals with. The user interface (page 908) of a program includes every program aspect the user comes into contact with: the syntax and semantics involved in invoking the program, the input and output of the program, and its error and informational messages. The shell and each of the utilities and built-in commands have a user interface.

International Organization for Standardization

See [ISO]

internet

A large network that encompasses other, smaller networks.

Internet

The largest internet in the world. The Internet (uppercase "I") is a multilevel hierarchy composed of
backbone networks (ARPANET, NSFnet, MILNET, and others), midlevel networks, and stub networks. These include commercial (.com or .co), university (.ac or .edu), research (.org or .net), and military (.mil) networks and span many different physical networks around the world with various protocols, including the Internet Protocol (IP). Outside the United States, country code domains are popular (.us, .es, .mx, .de, and so forth), although you will see them used within the United States as well.

**Internet Protocol**

See [IP]

**Internet Service Provider**

See [ISP]

**intranet**

An inhouse network designed to serve a group of people such as a corporation or school. The general public on the Internet does not have access to the intranet.

**invisible file**

A file whose filename starts with a period. These files are called invisible because the `ls` utility does not normally list them. Use the `la` option of `ls` to list all files, including invisible ones. The shell does not expand a leading asterisk (*) in an ambiguous file reference to match the filename of an invisible file. Also *hidden file*.

**IP**

Internet Protocol. The network layer for TCP/IP. IP is a best-effort, packet-switching, *connectionless protocol* (page 869) that provides packet routing, fragmentation, and reassembly through the data link layer. IPv4 is slowly giving way to IPv6. [FOLDOC]

**IP address**

Internet Protocol address. A four-part address associated with a particular network connection for a system using the Internet Protocol (IP). A system that is attached to multiple networks that use the IP will have a different IP address for each network interface.

**IP multicast**

See [multicast]
IP spoofing

A technique used to gain unauthorized access to a computer. The would-be intruder sends messages to the target machine. These messages contain an IP address indicating that the messages are coming from a trusted host. The target machine responds to the messages, giving the intruder (privileged) access to the target.

IPC

Interprocess communication. A method to communicate specific information between programs.

IPv4

IP version 4.

See also [IP]
See also [IPv6]

IPv6

IP version 6. The next generation of Internet Protocol, which provides a much larger address space (2^{128} bits versus 2^{32} bits for IPv4) that is designed to accommodate the rapidly growing number of Internet addressable devices. IPv6 also has built-in autoconfiguration, enhanced security, better multicast support, and many other features.

ISDN

Integrated Services Digital Network. A set of communications standards that allows a single pair of digital or standard telephone wires to carry voice, data, and video at a rate of 64 kilobits per second.

ISO

International Organization for Standardization. A voluntary, nontreaty organization founded in 1946. It is responsible for creating international standards in many areas, including computers and communications. Its members are the national standards organizations of 89 countries, including the American National Standards Institute. FOLDOC

ISO9660

The ISO standard defining a filesystem for CD-ROMs.
ISP

Internet service provider. Provides Internet access to its customers.

job control

A facility that enables you to move commands from the foreground to the background and vice versa. Job control enables you to stop commands temporarily.

journaling filesystem

A filesystem that maintains a noncached log file, or journal, which records all transactions involving the filesystem. When a transaction is complete, it is marked as complete in the log file.

The log file results in greatly reduced time spent recovering a filesystem after a crash, making it particularly valuable in systems where high availability is an issue.

JPEG

Joint Photographic Experts Group. This committee designed the standard image-compression algorithm. JPEG is intended for compressing either full-color or gray-scale digital images of natural, real-world scenes and does not work as well on nonrealistic images, such as cartoons or line drawings. Filename extensions: .jpg, jpeg.

justify

To expand a line of type in the process of formatting text. A justified line has even margins. A line is justified by increasing the space between words and sometimes between letters on the line.

Kerberos

An MIT-developed security system that authenticates users and machines. It does not provide authorization to services or databases; it establishes identity at logon, which is used throughout the session. Once you are authenticated, you can open as many terminals, windows, services, or other network accesses as you like until your session expires.

kernel

The part of the operating system that allocates machine resources, including memory, disk space, and CPU (page 869) cycles, to all other programs that run on a computer. The kernel includes the low-level hardware interfaces (drivers) and manages processes (page 894), the means by which Linux executes programs. The kernel is the part of the Linux system that Linus Torvalds originally wrote (see the beginning of Chapter 1).
kernelspace

The part of memory (RAM) where the kernel resides. Code running in kernelspace has full access to hardware and all other processes in memory. See the *KernelAnalysis-HOWTO*. 

key binding

A *keyboard* key is said to be bound to the action that results from pressing it. Typically keys are bound to the letters that appear on the keycaps: When you press A, an A appears on the screen. Key binding usually refers to what happens when you press a combination of keys, one of which is CONTROL, ALT, META, or SHIFT, or when you press a series of keys, the first of which is typically ESCAPE. 

keyboard

A hardware input device consisting of a number of mechanical buttons (keys) that the user presses to input characters to a computer. By default a keyboard is connected to standard input of a shell. 

kilo-

In the binary system, the prefix *kilo-* multiplies by $2^{10}$ (i.e., 1,024). Kilobit and kilobyte are common uses of this prefix. Abbreviated as k. 

Korn Shell

*ksh*. A command processor, developed by David Korn at AT&T Bell Laboratories, that is compatible with the Bourne Shell but includes many extensions. 

See also [shell]

LAN

Local area network. A network that connects computers within a localized area (such as a single site, building, or department). 

large number

Go to [mathworld.wolfram.com/LargeNumber.html](http://mathworld.wolfram.com/LargeNumber.html) for a comprehensive list.
LDAP

Lightweight Directory Access Protocol. A simple protocol for accessing online directory services. Traditionally LDAP has been used to access information such as email directories; in some cases, it can be used as an alternative for services such as NIS. Given a name, many mail clients can use LDAP to discover the corresponding email address.

See also [directory service]

leaf

In a tree structure, the end of a branch that cannot support other branches. When the Linux filesystem hierarchy is conceptualized as a tree, files that are not directories are leaves.

See also [node]

least privilege, concept of

Mistakes that Superuser makes can be much more devastating than those made by an ordinary user. When you are working on the computer, especially when you are working as the system administrator, always perform any task using the least privilege possible. If you can perform a task logged in as an ordinary user, do so. If you must be logged in as Superuser, do as much as you can as an ordinary user, log in as `su` so that you are Superuser, do as much of the task that has to be done as Superuser, and revert to being an ordinary user as soon as you can.

Because you are more likely to make a mistake when you are rushing, this concept becomes more important when you have less time to apply it. Also `root` user or just `root`.

Lightweight Directory Access Protocol

See [LDAP]

link

A pointer to a file. Two kinds of links exist: hard links and symbolic (soft) links. A hard link associates a filename with a place on the disk where the contents of the file is located. A symbolic link associates a filename with the pathname of a hard link to a file.

See also [hard link]
See also [symbolic link]

Linux-PAM

See [PAM]
Linux-Pluggable Authentication Modules

See [PAM]

loadable kernel module

See [loadable module]

loadable module

A portion of the operating system that controls a special device and that can be loaded automatically into a running kernel as needed to access that device.

local area network

See [LAN]

locale

The language; date, time, and currency formats; character sets; and so forth that pertain to a geopolitical place or area. For example, en_US specifies English as spoken in the United States and dollars; en_UK specifies English as spoken in the United Kingdom and pounds. See the locale (5) man page for more information. Also the locale utility.

log in

To gain access to a computer system by responding correctly to the login: and Password: prompts. Also log on, login.

log out

To end your session by exiting from your login shell. Also log off.

logical expression

A collection of strings separated by logical operators (>, >=, =, !=, <=, and <) that can be evaluated as true or false. Also Boolean expression.

.login file

A file in a user's home directory that the TC Shell executes when you log in. You can use this file to set
environment variables and to run commands that you want executed at the beginning of each session.

**login name**

The name you enter in response to the **login:** prompt. Other users use your login name when they send you mail or write to you. Each login name has a corresponding user ID, which is the numeric identifier for the user. Both the login name and the user ID are stored in the **passwd** database (**/etc/passwd** or the NIS equivalent).

**login shell**

The shell that you are using when you log in. The login shell can fork other processes that can run other shells, utilities, and programs.

**logout file**

A file in a user's home directory that the TC Shell executes when you log out, assuming that the TC Shell is your login shell. You can put in the **.logout** file commands that you want run each time you log out.

**MAC address**

Media Access Control address. The unique hardware address of a device connected to a shared network medium. Each Ethernet adapter has a globally unique MAC address in ROM. MAC addresses are 6 bytes long, enabling \(256^6\) (about 300 trillion) possible addresses or 65,536 addresses for each possible IPv4 address.

A MAC address performs the same role for Ethernet that an IP address performs for TCP/IP: It provides a unique way to identify a host.

**machine collating sequence**

The sequence in which the computer orders characters. The machine collating sequence affects the outcome of sorts and other procedures that put lists in alphabetical order. Many computers use ASCII codes so their machine collating sequences correspond to the ordering of the ASCII codes for characters.

**macro**

A single instruction that a program replaces by several (usually more complex) instructions. The C compiler recognizes macros, which are defined using a **#define** instruction to the preprocessor.
**magic number**

A magic number, which occurs in the first 512 bytes of a binary file, is a 1-, 2-, or 4-byte numeric value or character string that uniquely identifies the type of file (much like a DOS 3-character filename extension). See `/usr/share/magic` and the magic man page (5) for more information.

**main memory**

Random access memory (RAM), an integral part of the computer. Although disk storage is sometimes referred to as memory, it is never referred to as main memory.

**major device number**

A number assigned to a class of devices, such as terminals, printers, or disk drives. Using the `ls` utility with the `-l` option to list the contents of the `/dev` directory displays the major and minor device numbers of many devices (as major, minor).

**MAN**

Metropolitan area network. A network that connects computers and LANs (page 884) at multiple sites in a small regional area, such as a city.

**masquerade**

To appear to come from one domain or IP address when actually coming from another. Said of a packet (`iptables`) or message (`sendmail`).

**MD5**

Message Digest 5. A one-way hash function (page 891).

**MDA**

Mail delivery agent. One of the three components of a mail system; the other two are the MTA and MUA. An MDA accepts inbound mail from an MTA and delivers it to a local user.

**mega-**

In the binary system, the prefix mega- multiplies by $2^{20}$ (i.e., 1,048,576). Megabit and megabyte are common uses of this prefix. Abbreviated as $M$. 
**menu**

A list from which the user may select an operation to be performed. This selection is often made with a mouse or other pointing device under a GUI but may also be controlled from the keyboard. Very convenient for beginners, menus show which commands are available and facilitate experimenting with a new program, often reducing the need for user documentation. Experienced users usually prefer keyboard commands, especially for frequently used operations, because they are faster to use.

**merge**

To combine two ordered lists so that the resulting list is still in order. The `sort` utility can merge files.

**META key**

On the keyboard, a key that is labeled META or ALT. Use this key as you would the SHIFT key. While holding it down, press another key. The emacs editor makes extensive use of the META key.

**metacharacter**

A character that has a special meaning to the shell or another program in a particular context. Metacharacters are used in the ambiguous file references recognized by the shell and in the regular expressions recognized by several utilities. You must quote a metacharacter if you want to use it without invoking its special meaning.

See also [regular character]
See also [special character]

**metadata**

Data about data. In data processing, metadata is definitional data that provides information about, or documentation of, other data managed within an application or environment.

For example, metadata can document data about data elements or attributes (name, size, data type, and so on), records or data structures (page 870) (length, fields, columns, and so on), and data itself (where it is located, how it is associated, who owns it, and so on). Metadata can include descriptive information about the context, quality and condition, or characteristics of the data.

**metropolitan area network**
See [MAN]

**MIME**

Multipurpose Internet Mail Extension. Originally used to describe how specific types of files that were attached to email were to be handled. Today MIME types describe how a file is to be opened or worked with, based on its filename extension.

**minimize**

See [iconify]

**minor device number**

A number assigned to a specific device within a class of devices.

See also [major device number]

**modem**

Modulator/demodulator. A peripheral device that modulates digital data into analog data for transmission over a voice-grade telephone line. Another modem demodulates the data at the other end.

**module**

See [loadable module]

**mount**

To make a filesystem accessible to system users. When a filesystem is not mounted, you cannot read from or write to files it contains.

**mount point**

A directory that you mount a local or remote filesystem on.

**mouse**

A device you use to point to a particular location on a display screen, typically so you can choose a menu item, draw a line, or highlight some text. You control a pointer on the screen by sliding a mouse around on a flat surface; the position of the pointer moves relative to the movement of the mouse. You select items by pressing one or more buttons on the mouse.
mouse pointer

In a GUI, a marker that moves in correspondence with the mouse. It is usually a small black X with a white border or an arrow. Differs from the cursor (page 870).

mouseover

The action of passing the mouse pointer over an icon or other object on the screen.

MTA

Mail transfer agent. One of the three components of a mail system; the other two are the MDA and MUA. An MTA accepts mail from users and MTAs.

MUA

Mail user agent. One of the three components of a mail system; the other two are the MDA and MTA. An MUA is an end-user mail program such as Kmail, mutt, or Outlook.

multiboot specification

Specifies an interface between a boot loader and an operating system. With compliant boot loaders and operating systems, any boot loader should be able to load any operating system. The object of this specification is to ensure that different operating systems will work on a single machine. For more information, go to odin-os.sourceforge.net/guides/multiboot.html.

multicast

A multicast packet has one source and multiple destinations. In multicast, source hosts register at a special address to transmit data. Destination hosts register at the same address to receive data. In contrast to broadcast (page 865), which is LAN-based, multicast traffic is designed to work across routed networks on a subscription basis. Multicast reduces network traffic by transmitting a packet one time, with the router at the end of the path breaking it apart as needed for multiple recipients.

multitasking

A computer system that allows a user to run more than one job at a time. A multitasking system, such as Linux, allows you to run a job in the background while running a job in the foreground.
multiuser system

A computer system that can be used by more than one person at a time. Linux is a multiuser operating system. Contrast with single-user system (page 900).

NAT

Network Address Translation. A scheme that enables a LAN to use one set of IP addresses internally and a different set externally. The internal set is for LAN (private) use. The external set is typically used on the Internet and is Internet unique. NAT provides some privacy by hiding internal IP addresses and allows multiple internal addresses to connect to the Internet through a single external IP address.

NBT

NetBIOS over TCP/IP. A protocol that supports NetBIOS services in a TCP/IP environment. Also NetBT.

NetBIOS

Network Basic Input/Output System. An API (page 861) for writing network-aware applications.

netboot

To boot a computer over the network (as opposed to booting from a local disk).

netiquette

The conventions of etiquette—that is, polite behavior—recognized on Usenet and in mailing lists, such as not (cross-)posting to inappropriate groups and refraining from commercial advertising outside the business groups.

The most important rule of netiquette is "Think before you post." If what you intend to post will not make a positive contribution to the newsgroup and be of interest to several readers, do not post it. Personal messages to one or two individuals should not be posted to newsgroups; use private email instead.

netmask

A 32-bit mask (for IPv4), that shows how an Internet address is to be divided into network, subnet, and host parts. The netmask has ones in the bit positions in the 32-bit address that are to be used for the network and subnet parts and zeros for the host part. The mask should contain at least the standard network portion (as determined by the address class). The subnet field should be contiguous with the network portion.
network address

The network portion (netid) of an IP address. For a class A network, it is the first byte, or segment, of the IP address; for a class B network, it is the first two bytes; and for a class C network, it is the first three bytes. In each case the balance of the IP address is the host address (hostid). Assigned network addresses are globally unique within the Internet. Also *network number*.

Network Filesystem

See [NFS]

Network Information Service

See [NIS]

network number

See [network address]

network segment

A part of an Ethernet or other network on which all message traffic is common to all nodes; that is, it is broadcast from one node on the segment and received by all others. This commonality normally occurs because the segment is a single continuous conductor. Communication between nodes on different segments is via one or more routers. FOLDOC

network switch

A connecting device in networks. Switches are increasingly replacing shared media hubs in an effort to increase bandwidth. For example, a 16-port 10BaseT hub shares the total 10 megabits per second bandwidth with all 16 attached nodes. By replacing the hub with a switch, both sender and receiver can take advantage of the full 10 megabits per second capacity. Each port on the switch can give full bandwidth to a single server or client station or to a hub with several stations. *Network switch* refers to a device with intelligence. Contrast with *hub* (page 880).

Network Time Protocol

See [NTP]

NFS
Network Filesystem. A remote filesystem designed by Sun Microsystems, available on computers from most UNIX system vendors.

**NIC**

Network interface card (or controller). An adapter circuit board installed in a computer to provide a physical connection to a network. FOLDOC

**NIS**

Network Information Service. A distributed service built on a shared database to manage system-independent information (such as login names and passwords).

**NIS domain name**

A name that describes a group of systems that share a set of NIS files. Different from domain name (page 873).

**NNTP**

Network News Transfer Protocol.

**node**

In a tree structure, the end of a branch that can support other branches. When the Linux filesystem hierarchy is conceptualized as a tree, directories are nodes.

See also [leaf]

**nonprinting character**

Also nonprintable character.

See also [control character]

**nonvolatile storage**

A storage device whose contents are preserved when its power is off. Also NVS and persistent storage. Some examples are CD-ROM, paper punch tape, hard disk, ROM (page 898), PROM (page 895), EPROM (page 874), and EEPROM (page 873). Contrast with RAM (page 896).
NTP

Network Time Protocol. Built on top of TCP/IP, NTP maintains accurate local time by referring to known accurate clocks on the Internet.

null string

A string that could contain characters but does not. A string of zero length.

octal number

A base 8 number. Octal numbers are composed of the digits 0–7, inclusive. Refer to Table G-1 on page 879.

one-way hash function

A one-way function that takes a variable-length message and produces a fixed-length hash. Given the hash, it is computationally infeasible to find a message with that hash; in fact, you cannot determine any usable information about a message with that hash. Also message digest function.

OpenSSH

A free version of the SSH (secure shell) protocol suite that replaces TELNET, rlogin, and more with secure programs that encrypt all communication—even passwords—over a network.

operating system

A control program for a computer that allocates computer resources, schedules tasks, and provides the user with a way to access resources.

option

A command line argument that modifies the effects of a command. Options are usually preceded by hyphens on the command line and traditionally have single-character names (such as `-h` or `-n`). Some commands allow you to group options following a single hyphen (for example, `-hn`). GNU utilities frequently have two arguments that do the same thing: a single-character argument and a longer, more descriptive argument that is preceded by two hyphens (such as `--show-all` and `--invert-match`).
**ordinary file**

A file that is used to store a program, text, or other user data.

See also [directory]
See also [device file]

**output**

Information that a program sends to the terminal or another file.

See also [standard output]

**P2P**

Peer-to-Peer. A network that does not divide nodes into clients and servers. Each computer on a P2P network can fulfill the roles of client and server. In the context of a file-sharing network, this ability means that once a node has downloaded (part of) a file, it can act as a server. BitTorrent implements a P2P network.

**packet**

A unit of data sent across a network. Packet is a generic term used to describe a unit of data at any layer of the OSI protocol stack, but it is most correctly used to describe network or application layer data units ("application protocol data unit," APDU). [FOLDOC]

See also [frame]
See also [datagram]

**packet filtering**

A technique used to block network traffic based on specified criteria, such as the origin, destination, or type of each packet.

See also [firewall]

**packet sniffer**

A program or device that monitors packets on a network.

See also [sniff]
pager

A utility that allows you to view a file one screen at a time (for example, `less` and `more`).

paging

The process by which virtual memory is maintained by the operating system. The contents of process memory is moved (paged out) to the swap space (page 904) as needed to make room for other processes.

PAM

Linux-PAM or Linux-Pluggable Authentication Modules. These modules allow a system administrator to determine how various applications authenticate users.

parent process

A process that forks other processes.

See also [process]

See also [child process]

partition

A section of a (hard) disk that has a name so you can address it separately from other sections. A disk partition can hold a filesystem or another structure, such as the swap area. Under DOS and Windows, partitions (and sometimes whole disks) are labeled C:, D:, and so on. Also disk partition and slice.

passive FTP

Allows FTP to work through a firewall by allowing the flow of data to be initiated and controlled by the client FTP program instead of the server. Also called PASV FTP because it uses the FTP PASV command.

passphrase

A string of words and characters that you type in to authenticate yourself. A passphrase differs from a password only in length. A password is usually short—6 to 10 characters. A passphrase is usually much longer—up to 100 characters or more. The greater length makes a passphrase harder to guess or reproduce than a password and therefore more secure. FOLDOC
password

To prevent unauthorized access to a user’s account, an arbitrary string of characters chosen by the user or system administrator and used to authenticate the user when attempting to log in. [FOLDOC]

See also [passphrase]

PASV FTP

See [passive FTP]

pathname

A list of directories separated by slashes (/) and ending with the name of a file, which can be a directory. A pathname is used to trace a path through the file structure to locate or identify a file.

pathname, last element of a

The part of a pathname following the final /, or the whole filename if there is no /. A simple filename. Also basename.

pathname element

One of the filenames that forms a pathname.

peripheral device

See [device]

persistent

Data that is stored on nonvolatile media, such as a hard disk.

physical device

A tangible device, such as a disk drive, that is physically separate from other, similar devices.

PID

Process identification, usually followed by the word number. Linux assigns a unique PID number as each
Process identification, usually followed by the word number. Linux assigns a unique PID number as each process is initiated.

pipe

A connection between programs such that standard output of one program is connected to standard input of the next. Also pipeline.

pixel

The smallest element of a picture, typically a single dot on a display screen.

plaintext

Text that is not encrypted. Also cleartext. Contrast with ciphertext (page 867).

Pluggable Authentication Modules

See [PAM]

point-to-point link

A connection limited to two endpoints, such as the connection between a pair of modems.

port

A logical channel or channel endpoint in a communications system. The TCP (page 905) and UDP (page 907) transport layer protocols used on Ethernet use port numbers to distinguish between different logical channels on the same network interface on the same computer.

The /etc/services file (see the beginning of this file for more information) or the NIS (page 890) services database specifies a unique port number for each application program. The number links incoming data to the correct service (program). Standard, well-known ports are used by everyone: Port 80 is used for HTTP (Web) traffic. Some protocols, such as TELNET and HTTP (which is a special form of TELNET), have default ports specified as mentioned earlier but can use other ports as well. FOLDOC

port forwarding

The process by which a network port on one computer is transparently connected to a port on another computer. If port X is forwarded from system A to system B, any data sent to port X on system A is sent to system B automatically. The connection can be between different ports on the two systems.
portmapper

A server that converts TCP/IP port numbers into RPC (page 899) program numbers.

printable character

One of the graphic characters: a letter, number, or punctuation mark. Contrast with a nonprintable, or control, character. Also printing character.

private address space

IANA (page 880) has reserved three blocks of IP addresses for private internets or LANs:

- 10.0.0.0 - 10.255.255.255
- 172.16.0.0 - 172.31.255.255
- 192.168.0.0 - 192.168.255.255

You can use these addresses without coordinating with anyone outside of your LAN (you do not have to register the system name or address). Systems using these IP addresses cannot communicate directly with hosts using the global address space but must go through a gateway. Because private addresses have no global meaning, routing information is not stored by DNSs and most ISPs reject privately addressed packets. Make sure that your router is set up not to forward these packets onto the Internet.

privileged port

A port (page 893) with a number less than 1,024. On Linux and other UNIX-like systems, only root can bind to a privileged port. Any user on Windows 98 and earlier Windows systems can bind to any port.

procedure

A sequence of instructions for performing a particular task. Most programming languages, including machine languages, enable a programmer to define procedures that allow the procedure code to be called from multiple places. Also subroutine. FOLDOC

process

The execution of a command by Linux. See "Processes" on page 292.
.profile file

A startup file in a user's home directory that the Bourne Again Shell executes when you log in. The TC Shell executes `.login` instead. You can use the `.profile` file to run commands, set variables, and define functions.

program

A sequence of executable computer instructions contained in a file. Linux utilities, applications, and shell scripts are all programs. Whenever you run a command that is not built into a shell, you are executing a program.

PROM

Programmable readonly memory. A kind of nonvolatile storage. ROM (page 898) that can be written to using a PROM programmer.

prompt

A cue from a program, usually displayed on the screen, indicating that it is waiting for input. The shell displays a prompt, as do some of the interactive utilities, such as `mail`. By default the Bourne Again and Z Shells use a dollar sign ($) as a prompt, and the TC Shell uses a percent sign (%).

protocol

A set of formal rules describing how to transmit data, especially across a network. Low-level protocols define the electrical and physical standards, bit and byte ordering, and transmission, error detection, and correction of the bit stream. High-level protocols deal with data formatting, including message syntax, terminal-to-computer dialog, character sets, and sequencing of messages. 

proxy

A service that is authorized to act for a system while not being part of that system.

See also [proxy gateway]
See also [proxy server]

proxy gateway

A computer that separates clients (such as browsers) from the Internet, working as a trusted agent that
A computer that separates clients (such as browsers) from the Internet, working as a trusted agent that accesses the Internet on their behalf. A proxy gateway passes a request for data from an Internet service, such as HTTP from a browser/client, to a remote server. The data that the server returns goes back through the proxy gateway to the requesting service. A proxy gateway should be transparent to the user.

A proxy gateway often runs on a firewall system and acts as a barrier to malicious users. It hides the IP addresses of the local computers inside the firewall from Internet users outside the firewall.

You can configure browsers, such as Mozilla and Netscape, to use a different proxy gateway or to use no proxy for each URL access method including FTP, netnews, SNMP, HTTPS, and HTTP.

See also [proxy]

proxy server

A proxy gateway that usually includes a cache that holds frequently used Web pages so that the next request for that page is available locally (and therefore more quickly). The terms proxy server and proxy gateway are frequently interchanged so that the use of cache does not rest exclusively with the proxy server.

See also [proxy]

Python

A simple, high-level, interpreted, object-oriented, interactive language that bridges the gap between C and shell programming. Suitable for rapid prototyping or as an extension language for C applications, Python supports packages, modules, classes, user-defined exceptions, a good C interface, and dynamic loading of C modules. It has no arbitrary restrictions. For more information, see www.python.org.

quote

When you quote a character, you take away any special meaning that it has in the current context. You can quote a character by preceding it with a backslash. When you are interacting with the shell, you can also quote a character by surrounding it with single quotation marks. For example, the command `echo \*` or `echo '('* displays *. The command `echo *` displays a list of the files in the working directory. Also `escape`.

See also [ambiguous file reference]
See also [metacharacter]
See also [regular character]
See also [regular expression]
See also [special character]

radio button

One of a group of buttons similar to those used to select the station on a radio. Only one button can be selected at a time.
RAID

Redundant array of inexpensive/independent disks. Two or more (hard) disk drives used in combination to improve fault tolerance and performance. RAID can be implemented in hardware or software.

RAM

Random access memory. A kind of volatile storage. A data storage device for which the order of access to different locations does not affect the speed of access. Contrast with a hard disk or tape drive, which provides quicker access to sequential data because accessing a nonsequential location requires physical movement of the storage medium and/or read/write head rather than just electronic switching. Contrast with nonvolatile storage (page 891). FOLDOC

RAM disk

RAM that is made to look like a floppy diskette or hard disk. A RAM disk is frequently used as part of the boot (page 864) process.

RAS

Remote access server. In a network, a computer that provides access to remote users via analog modem or ISDN connections. RAS includes the dial-up protocols and access control (authentication). It may be a regular file server with remote access software or a proprietary system, such as Shiva's LANRover. The modems may be internal or external to the device.

RDF

Resource Description Framework. Being developed by W3C (the main standards body for the World Wide Web), a standard that specifies a mechanism for encoding and transferring metadata (page 887). RDF does not specify what the metadata should or can be. It can integrate many kinds of applications and data, using XML as an interchange syntax. Examples of the data that can be integrated include library catalogs and worldwide directories; syndication and aggregation of news, software, and content; and collections of music and photographs. Go to www.w3.org/RDF for more information.

direction

The process of directing standard input for a program to come from a file rather than from the keyboard. Also, directing standard output or standard error to go to a file rather than to the screen.

reentrant
Code that can have multiple simultaneous, interleaved, or nested invocations that do not interfere with one another. Noninterference is important for parallel processing, recursive programming, and interrupt handling.

It is usually easy to arrange for multiple invocations (that is, calls to a subroutine) to share one copy of the code and any readonly data. For the code to be reentrant, however, each invocation must use its own copy of any modifiable data (or synchronized access to shared data). This goal is most often achieved by using a stack and allocating local variables in a new stack frame for each invocation. Alternatively, the caller may pass in a pointer to a block of memory that that invocation can use (usually for output), or the code may allocate some memory on a heap, especially if the data must survive after the routine returns.

Reentrant code is often found in system software, such as operating systems and teleprocessing monitors. It is also a crucial component of multithreaded programs, where the term thread-safe is often used instead of reentrant.  

**regular character**

A character that always represents itself in an ambiguous file reference or another type of regular expression. Contrast with special character.

**regular expression**

A string composed of letters, numbers, and special symbols that defines one or more strings. See Appendix A.

**relative pathname**

A pathname that starts from the working directory. Contrast with absolute pathname (page 860).

**remote access server**

See [RAS]

**remote filesystem**

A filesystem on a remote computer that has been set up so that you can access (usually over a network) its files as though they were stored on your local computer's disks. An example of a remote filesystem is NFS.

**remote procedure call**

See [RPC]
resolver

The TCP/IP library software that formats requests to be sent to the DNS (page 872) for hostname-to-Internet address conversion.  

Resource Description Framework

See [RDF]

restore

The process of turning an icon into a window. Contrast with iconify (page 880)

return code

See [exit status]

RFC

Request for comments. Begun in 1969, one of a series of numbered Internet informational documents and standards widely followed by commercial software and freeware in the Internet and UNIX/Linux communities. Few RFCs are standards but all Internet standards are recorded in RFCs. Perhaps the single most influential RFC has been RFC 822, the Internet electronic mail format standard.

The RFCs are unusual in that they are floated by technical experts acting on their own initiative and reviewed by the Internet at large rather than being formally promulgated through an institution such as ANSI. For this reason they remain known as RFCs, even after they are adopted as standards. The RFC tradition of pragmatic, experience-driven, after-the-fact standard writing done by individuals or small working groups has important advantages over the more formal, committee-driven process typical of ANSI or ISO. For a complete list of RFCs, go to www.rfc-editor.org.  

roam

To move a computer between wireless access points (page 910) on a wireless network without the user or applications being aware of the transition. Moving between access points typically results in some packet loss, although this loss is transparent to programs that use TCP.

ROM

Readonly memory. A kind of nonvolatile storage. A data storage device that is manufactured with fixed contents. In general, ROM describes any storage system whose contents cannot be altered, such as a phonograph record or printed book. When used in reference to electronics and computers, ROM describes semiconductor integrated circuit memories, of which several types exist, and CD-ROM.
ROM is nonvolatile storage; it retains its contents even after power has been removed. ROM is often used to hold programs for embedded systems, as these usually have a fixed purpose. ROM is also used for storage of the BIOS (page 863) in a computer. Contrast with RAM (page 896). FOldOC

**root directory**

The ancestor of all directories and the start of all absolute pathnames. The name of the root directory is `/.`

**root filesystem**

The filesystem that is available when the system is brought up in single-user mode. The name of this filesystem is always `/`. You cannot unmount or mount the root filesystem. You can remount root to change its `mount` options.

**root login**

Usually the login name of Superuser (page 904).

**root (user)**

Another name for Superuser (page 904).

**rotate**

When a file, such as a log file, gets indefinitely larger, you must keep it from taking up too much space on the disk. Because you may need to refer to the information in the log files in the near future, it is generally not a good idea to delete the contents of the file until it has aged. Instead you can periodically save the current log file under a new name and create a new, empty file as the current log file. You can keep a series of these files, renaming each as a new one is saved. You will then rotate the files. For example, you might remove `xyzlog.4, xyzlog.3 ➔ xyzlog.4, xyzlog.2 ➔ xyzlog.3, xyzlog.1 ➔ xyzlog.2, xyzlog ➔ xyzlog.1`, and create a new `xyzlog` file. By the time you remove `xyzlog.4`, it will not contain any information more recent than you want to remove.

**router**

A device (often a computer) that is connected to more than one similar type of network to pass data between them.

See also [gateway]
**RPC**

Remote procedure call. A call to a *procedure* (page 894) that acts transparently across a network. The procedure itself is responsible for accessing and using the network. The RPC libraries make sure that network access is transparent to the application. RPC runs on top of TCP/IP or UDP/IP.

**RSA**

A public key encryption technology that is based on the lack of an efficient way to factor very large numbers. Because of this lack, it takes an extraordinary amount of computer processing time and power to deduce an RSA key. The RSA algorithm is the de facto standard for data sent over the Internet.

**run**

To execute a program.

**Samba**

A free suite of programs that implement the Server Message Block (SMB) protocol.

See also [SMB](#)

**schema**

Within a GUI, a pattern that helps you see and interpret the information that is presented in a window, making it easier to understand new information that is presented using the same schema.

**scroll**

To move lines on a terminal or window up and down or left and right.

**scrollbar**

A widget found in graphical user interfaces that controls (scrolls) which part of a document is visible in the window. A window can have a horizontal scroll bar, a vertical scroll bar (more common), or both.

**server**

A powerful centralized computer (or program) designed to provide information to clients (smaller computers or programs) on request.
session

The lifetime of a process. For a desktop, it is the desktop session manager. For a character-based terminal, it is the user's login shell process. In KDE, it is launched by `kdeinit`. A session may also be the sequence of events between when you start using a program, such as an editor, and when you finish.

setgid

When you execute a file that has setgid (set group ID) permission, the process executing the file takes on the privileges of the group the file belongs to. The `ls` utility shows setgid permission as an `s` in the group's executable position.

See also [setuid]

setuid

When you execute a file that has setuid (set user ID) permission, the process executing the file takes on the privileges of the owner of the file. As an example, if you run a setuid program that removes all the files in a directory, you can remove files in any of the file owner's directories, even if you do not normally have permission to do so. When the program is owned by root, you can remove files in any directory that root can remove files from. The `ls` utility shows setuid permission as an `s` in the owner's executable position.

See also [setgid]

sexillion

In the British system, $10^{36}$. In the American system, this number is named undecillion.

See also [large number]

share

A directory and the filesystem hierarchy below it that are shared with another system using SMB (page 901). Also Windows share (page 910).

shared network topology

A network, such as Ethernet, in which each packet may be seen by systems other than its destination system. Shared means that the network bandwidth is shared by all users.
shell

A Linux system command processor. The three major shells are the Bourne Again Shell (page 864), the TC Shell (page 905), and the Z Shell (page 911).

shell function

A series of commands that the shell stores for execution at a later time. Shell functions are like shell scripts but run more quickly because they are stored in the computer's main memory rather than in files. Also, a shell function is run in the environment of the shell that calls it (unlike a shell script, which is typically run in a subshell).

shell script

An ASCII file containing shell commands. Also shell program.

signal

A very brief message that the UNIX system can send to a process, apart from the process's standard input. Refer to "trap: Catches a Signal" on page 493.

simple filename

A single filename containing no slashes (/). A simple filename is the simplest form of pathname. Also the last element of a pathname. Also basename (page 863).

single-user system

A computer system that only one person can use at a time. Contrast with multiuser system (page 889).

SMB

Server Message Block. Developed in the early 1980s by Intel, Microsoft, and IBM, SMB is a client/server protocol that is the native method of file and printer sharing for Windows. In addition, SMB can share serial ports and communications abstractions, such as named pipes and mail slots. SMB is similar to a remote procedure call (RPC; page 899) that has been customized for filesystem access. Also Microsoft Networking.

smiley
A character-based *glyph* (page 877), typically used in email, that conveys an emotion. The characters :-) in a message portray a smiley face (look at it sideways). Because it can be difficult to tell when the writer of an electronic message is saying something in jest or in seriousness, email users often use :-) to indicate humor. The two original smileys, designed by Scott Fahlman, were :-) and :-(. Also *emoticon*, *smileys*, and *smilies*. For more information search on smiley on the Internet.

**smilies**

See [smiley]

**SMTP**

Simple Mail Transfer Protocol. A protocol used to transfer electronic mail between computers. It is a server-to-server protocol, so other protocols are used to access the messages. The SMTP dialog usually happens in the background under the control of a message transport system such as sendmail.  

**snap (windows)**

As you drag a window toward another window or edge of the workspace, it can move suddenly so that it is adjacent to the other window/edge. Thus the window snaps into position.

**sneakernet**

Using hand-carried magnetic media to transfer files between machines.

**sniff**

To monitor packets on a network. A system administrator can legitimately sniff packets and a malicious user can sniff packets to obtain information such as usernames and passwords.

See also [packet sniffer]

**SOCKS**

A networking proxy protocol embodied in a SOCKS server, which performs the same functions as a *proxy gateway* (page 895) or *proxy server* (page 895). SOCKS works at the application level, requiring that an application be modified to work with the SOCKS protocol, whereas a *proxy* (page 895) makes no demands on the application.

SOCKSv4 does not support authentication or UDP proxy. SOCKSv5 supports a variety of authentication methods and UDP proxy.
sort

To put in a specified order, usually alphabetic or numeric.

**SPACE character**

A character that appears as the absence of a visible character. Even though you cannot see it, a **SPACE** is a printable character. It is represented by the ASCII code 32 (decimal). A **SPACE** character is considered a *blank or whitespace* (page 909).

spam

Posting irrelevant or inappropriate messages to one or more Usenet newsgroups or mailing lists in deliberate or accidental violation of *netiquette* (page 889). Also, sending large amounts of unsolicited email indiscriminately. This email usually promotes a product or service. Spam is the electronic equivalent of junk mail. From the Monty Python "Spam" song. [FOLDOC](https://www.freedictionary.org)

sparse file

A file that is large but takes up little disk space. The data in a sparse file is not dense (thus its name). Examples of sparse files are core files, dbm files, and `/etc/utmp` ([`/var/adm/utmp`)](https://www.freedictionary.org).

spawn

See [fork](https://www.freedictionary.org)

special character

A character that has a special meaning when it occurs in an ambiguous file reference or another type of regular expression, unless it is quoted. The special characters most commonly used with the shell are * and ?. Also *metacharacter* (page 887) and *wildcard*.

special file

See [device file](https://www.freedictionary.org)

spinner

In a GUI, a type of *text box* (page 905) that holds a number you can change by typing over it or using the up and down arrows at the end of the box.
spoofing

See [IP spoofing]

spool

To place items in a queue, each waiting its turn for some action. Often used when speaking about printers. Also used to describe the queue.

SQL

Structured Query Language. A language that provides a user interface to relational database management systems (RDBMS). SQL, the de facto standard, is also an ISO and ANSI standard and is often embedded in other programming languages.  

square bracket

A left square bracket ( [ ) or a right square bracket ( ] ). These special characters define character classes in ambiguous file references and other regular expressions.

SSH Communications Security

The company that created the original SSH (secure shell) protocol suite (www.ssh.com). Linux uses OpenSSH.

See also [OpenSSH]

standard error

A file to which a program can send output. Usually only error messages are sent to this file. Unless you instruct the shell otherwise, it directs this output to the screen (that is, to the device file that represents the screen).

standard input

A file from which a program can receive input. Unless you instruct the shell otherwise, it directs this input so that it comes from the keyboard (that is, from the device file that represents the keyboard).

standard output
A file to which a program can send output. Unless you instruct the shell otherwise, it directs this output to the screen (that is, to the device file that represents the screen).

**startup file**

A file that the login shell runs when you log in. The Bourne Again and Z Shells run `.profile`, and the TC Shell runs `.login`. The TC Shell also runs `.cshrc` whenever a new TC Shell or a subshell is invoked. The Z Shell runs an analogous file whose name is identified by the `ENV` variable.

**status line**

The bottom (usually the twenty-fourth) line of the terminal. The `vim` editor uses the status line to display information about what is happening during an editing session.

**sticky bit**

An access permission bit that causes an executable program to remain on the swap area of the disk. It takes less time to load a program that has its sticky bit set than one that does not. Only Superuser can set the sticky bit. If the sticky bit is set on a directory that is publicly writable, only the owner of a file in that directory can remove the file.

**streaming tape**

A tape that moves at a constant speed past the read/write heads rather than speeding up and slowing down, which can slow the process of writing to or reading from the tape. A proper blocking factor helps ensure that the tape device will be kept streaming.

**streams**

See [connection-oriented protocol]

**string**

A sequence of characters.

**stylesheet**

See [CSS]

**subdirectory**
A directory that is located within another directory. Every directory except the root directory is a subdirectory.

**subnet**

Subnetwork. A portion of a network, which may be a physically independent network segment, that shares a network address with other portions of the network and is distinguished by a subnet number. A subnet is to a network as a network is to an internet. [[FOLDOC]]

**subnet address**

The subnet portion of an IP address. In a subnetwork, the host portion of an IP address is split into a subnet portion and a host portion using a subnet mask (also address mask).

See also [subnet number]

**subnet mask**

A bit mask used to identify which bits in an IP address correspond to the network address and subnet portions of the address. Called a subnet mask because the network portion of the address is determined by the number of bits that are set in the mask. The subnet mask has ones in positions corresponding to the network and subnet numbers and zeros in the host number positions. Also address mask.

**subnet number**

The subnet portion of an IP address. In a subnetwork, the host portion of an IP address is split into a subnet portion and a host portion using a subnet mask (also address mask).

See also [subnet address]

**subpixel hinting**

Similar to anti-aliasing (page 861) but takes advantage of colors to do the anti-aliasing. Particularly useful on LCD screens.

**subroutine**

See [procedure]

**subshell**
A shell that is forked as a duplicate of its parent shell. When you run an executable file that contains a shell script by using its filename on the command line, the shell forks a subshell to run the script. Also, commands surrounded with parentheses are run in a subshell.

**superblock**

A block that contains control information for a filesystem. The superblock contains housekeeping information, such as the number of inodes in the filesystem and free list information.

**superserver**

The extended Internet services daemon.

**Superuser**

A privileged user having access to anything any other system user has access to and more. The system administrator must be able to become Superuser to establish new accounts, change passwords, and perform other administrative tasks. The login name of Superuser is usually `root`. Also `root` or `root user`.

**swap**

The operating system moving a process from main memory to a disk, or vice versa. Swapping a process to the disk allows another process to begin or continue execution.

**swap space**

An area of a disk (that is, a swap file) used to store the portion of a process's memory that has been paged out. Under a virtual memory system, the amount of swap space—rather than the amount of physical memory—determines the maximum size of a single process and the maximum total size of all active processes. Also swap area or swapping area. FOLDOC

**switch**

See [network switch]

**symbolic link**

A directory entry that points to the pathname of another file. In most cases a symbolic link to a file can be used in the same ways a hard link can be used. Unlike a hard link, a symbolic link can span filesystems and can connect to a directory.
**system administrator**

The person responsible for the upkeep of the system. The system administrator has the ability to log in as Superuser.

See also [Superuser]

**system console**

The main system terminal, usually directly connected to the computer and the one that receives system error messages. Also console and console terminal.

**system mode**

The designation for the state of the system while it is doing system work. Some examples are making system calls, running NFS and autos, processing network traffic, and performing kernel operations on behalf of the system. Contrast with user mode (page 908).

**System V**

One of the two major versions of the UNIX system.

**TC Shell**

**tcsh**. An enhanced but completely compatible version of the BSD UNIX C shell, csh.

**TCP**

Transmission Control Protocol. The most common transport layer protocol used on the Internet. This connection-oriented protocol is built on top of IP (page 882) and is nearly always seen in the combination TCP/IP (TCP over IP). TCP adds reliable communication, sequencing, and flow control and provides full-duplex, process-to-process connections. **UDP** (page 907), although connectionless, is the other protocol that runs on top of IP.  

**tera-**

In the binary system, the prefix tera- multiplies by $2^{40}$ (1,099,511,627,776). Terabyte is a common use of this prefix. Abbreviated as T.

See also [large number]
**termcap**

Terminal capability. The `/etc/termcap` file contains a list of various types of terminals and their characteristics. *System V* replaced the function of this file with the *terminfo* system.

**terminal**

Differentiated from a *workstation* (page 910) by its lack of intelligence, a terminal connects to a computer that runs Linux. A workstation runs Linux on itself.

**terminfo**

Terminal information. The `/usr/lib/terminfo` directory contains many subdirectories, each containing several files. Each of those files is named for and holds a summary of the functional characteristics of a particular terminal. Visually oriented text-based programs, such as *vim*, use these files. An alternative to the *termcap* file.

**text box**

In a GUI, a box you can type in.

**theme**

Defined as an implicit or recurrent idea, *theme* is used in a GUI to describe a look that is consistent for all elements of a desktop. Go to themes.freshmeat.net for examples.

**thicknet**

A type of coaxial cable (thick) used for an Ethernet network. Devices are attached to thicknet by tapping the cable at fixed points.

**thinnet**

A type of coaxial cable (thin) used for an Ethernet network. Thinnet cable is smaller in diameter and more flexible than *thicknet* cable. Each device is typically attached to two separate cable segments by using a T-shaped connector; one segment leads to the device ahead of it on the network and one to the device that follows it.
thread-safe

See [reentrant]

thumb

The movable button in the scrollbar that positions the image in the window. The size of the thumb reflects the amount of information in the buffer. Also bubble.

TIFF

Tagged Image File Format. A file format used for still-image bitmaps, stored in tagged fields. Application programs can use the tags to accept or ignore fields, depending on their capabilities. FOLDOC

tiled windows

An arrangement of windows such that no window overlaps another. The opposite of cascading windows (page 866).

time to live

See [TTL]

toggle

To switch between one of two positions. For example, the ftp glob command toggles the glob feature: Give the command once, and it turns the feature on or off; give the command again, and it sets the feature back to its original state.

token

A basic, grammatically indivisible unit of a language, such as a keyword, operator, or identifier. FOLDOC

token ring

A type of LAN (page 884) in which computers are attached to a ring of cable. A token packet circulates continuously around the ring. A computer can transmit information only when it holds the token.

tooltip
A minicontext help system that you activate by allowing your mouse pointer to hover (page 879) over a button, icon, or applet (such as those on a panel).

**transient window**

A dialog or other window that is displayed for only a short time.

**Transmission Control Protocol**

See [TCP]

**Trojan horse**

A program that does something destructive or disruptive to your system. Its action is not documented, and the system administrator would not approve of it if she were aware of it.

The term *Trojan horse* was coined by MIT-hacker-turned-NSA-spook Dan Edwards. It refers to a malicious security-breaking program that is disguised as something benign, such as a directory lister, archive utility, game, or (in one notorious 1990 case on the Mac) a program to find and destroy viruses. Similar to *back door* (page 862).  

**TTL**

Time to live.

1. All DNS records specify how long they are good for; usually up to a week at most. This time is called the record's *time to live*. When a DNS server or an application stores this record in *cache* (page 866), it decrements the TTL value and removes the record from cache when the value reaches zero. A DNS server passes a cached record to another server with the current (decremented) TTL guaranteeing the proper TTL, no matter how many servers the record passes through.

2. In the IP header, a field that indicates how many more hops the packet should be allowed to make before being discarded or returned.

**TTY**

Teletypewriter. The terminal device that UNIX was first run from. Today TTY refers to the screen (or window, in the case of a terminal emulator), keyboard, and mouse that are connected to a computer. This term appears in UNIX, and Linux has kept the term for the sake of consistency and tradition.

**tunneling**

Encapsulation of protocol A within packets carried by protocol B, such that A treats B as though it were a
Encapsulation of protocol A within packets carried by protocol B, such that A treats B as though it were a data link layer. Tunneling is used to transfer data between administrative domains that use a protocol not supported by the internet connecting those domains. It can also be used to encrypt data sent over a public internet, as when you use ssh to tunnel a protocol over the Internet.  

See also [VPN]

UDP

User Datagram Protocol. The Internet standard transport layer protocol that provides simple but unreliable datagram services. UDP is a connectionless protocol (page 869) that, like TCP (page 905), is layered on top of IP (page 882).

Unlike TCP, UDP neither guarantees delivery nor requires a connection. As a result it is lightweight and efficient, but the application program must handle all error processing and retransmission. UDP is often used for sending time-sensitive data that is not particularly sensitive to minor loss, such as audio and video data.

UID

User ID. A number that the passwd database associates with a login name.

undecillion

In the American system, $10^{36}$. In the British system, this number is named sexillion.

See also [large number]

unicast

A packet sent from one host to another host. Unicast means one source and one destination.

unmanaged window

See [ignored window]

URI

Uniform Resource Identifier. The generic set of all names and addresses that are short strings referring to objects (typically on the Internet). The most common kinds of URIs are URLs.

URL
Uniform (was Universal) Resource Locator. A standard way of specifying the location of an object, typically a Web page, on the Internet. URLs are a subset of URIs.

usage message

A message displayed by a command when you call the command using incorrect command line arguments.

User Datagram Protocol

See [UDP]

User ID

See [UID]

user interface

See [interface]

user mode

The designation for the state of the system while it is doing user work, such as running a user program (but not the system calls made by the program). Contrast with system mode (page 905).

userspace

The part of memory (RAM) where applications reside. Code running in userspace cannot access hardware directly and cannot access memory allocated to other applications. Also userland. See the KernelAnalysis-HOWTO.

UTC

Coordinated Universal Time. UTC is the equivalent to the mean solar time at the prime meridian (0 degrees longitude). Also called Zulu time (Z stands for longitude zero) and GMT (Greenwich Mean Time).

utility

A program included as a standard part of Linux. You typically invoke a utility either by giving a command in response to a shell prompt or by calling it from within a shell script. Utilities are often referred to as commands. Contrast with builtin (command) (page 865).
variable

A name and an associated value. The shell allows you to create variables and use them in shell scripts. Also, the shell inherits several variables when it is invoked, and it maintains those and other variables while it is running. Some shell variables establish characteristics of the shell environment; others have values that reflect different aspects of your ongoing interaction with the shell.

viewport

Same as workspace (page 910).

virtual console

Additional consoles, or displays, that you can view on the system, or physical, console.

virus

A cracker (page 869) program that searches out other programs and "infects" them by embedding a copy of itself in them, so that they become Trojan horses (page 906). When these programs are executed, the embedded virus is executed as well, propagating the "infection," usually without the user's knowledge. By analogy with biological viruses. FOLDOC

VLAN

Virtual LAN. A logical grouping of two or more nodes that are not necessarily on the same physical network segment but that share the same network number. A VLAN is often associated with switched Ethernet. FOLDOC

VPN

Virtual Private Network. A private network that exists on a public network, such as the Internet. A VPN is a less expensive substitute for company-owned/leased lines and uses encryption to ensure privacy. A nice side effect is that you can send non-Internet protocols, such as Appletalk, IPX, or NetBIOS, over the VPN connection by tunneling (page 907) them through the VPN IP stream.

W2K

Windows 2000 Professional or Server.
W3C

World Wide Web Consortium (www.w3.org).

WAN

Wide area network. A network that interconnects LANs (page 884) and MANs (page 886), spanning a large geographic area (typically states or countries).

WAP

See [wireless access point]

Web ring

A collection of Web sites that provide information on a single topic or group of related topics. Each home page that is part of the Web ring has a series of links that let you go from site to site.

whitespace

A collective name for SPACEs and/or TABs and occasionally NEWLINEs. Also white space.

wide area network

See [WAN]

widget

The basic objects of a graphical user interface. Buttons, text fields, and scrollbars are examples of widgets.

wild card

See [metacharacter]

Wi-Fi

Wireless Fidelity. A generic term that refers to any type of 802.11 (page 860) wireless network.

window
On a display screen, a region that runs or is controlled by a particular program.

**window manager**

A program that controls how windows appear on a display screen and how you manipulate them.

**Windows share**

See [share]

**WINS**

Windows Internet Naming Service. The service responsible for mapping NetBIOS names to IP addresses. WINS has the same relationship to NetBIOS names that DNS has to Internet domain names.

**WINS server**

The program responsible for handling WINS requests. This program caches name information about hosts on a local network and resolves them to IP addresses.

**wireless access point**

A bridge or router between wired and wireless networks. Wireless access points typically support some form of access control to prevent unauthorized clients from connecting to the network. Also WAP.

**word**

A sequence of one or more nonblank characters separated from other words by TABs, SPACES, or NEWLINEs. Used to refer to individual command line arguments. In **vim**, a word is similar to a word in the English language: a string of one or more characters bounded by a punctuation mark, a numeral, a TAB, a SPACE, or a NEWLINE.

**Work buffer**

A location where **vim** stores text while it is being edited. The information in the Work buffer is not written to the file on the disk until you give the editor a command to write it.

**working directory**
The directory that you are associated with at any given time. The relative pathnames you use are relative to the working directory. Also current directory.

**workspace**

A subdivision of a desktop (page 871) that occupies the entire display.

**workstation**

A small computer, typically designed to fit in an office and be used by one person and usually equipped with a bit-mapped graphical display, keyboard, and mouse. Differentiated from a terminal (page 905) by its intelligence. A workstation runs Linux on itself while a terminal connects to a computer that runs Linux.

**worm**

A program that propagates itself over a network, reproducing itself as it goes. Today the term has negative connotations, as it is assumed that only crackers (page 869) write worms. Compare to virus (page 909) and Trojan horse (page 906). From Tapeworm in John Brunner's novel, The Shockwave Rider, Ballantine Books, 1990 (via XEROX PARC).

**WYSIWYG**

What You See Is What You Get. A graphical application, such as a word processor, whose display is similar to its printed output.

**X terminal**

A graphics terminal designed to run the X Window System.

**X Window System**

A design and set of tools for writing flexible, portable windowing applications, created jointly by researchers at MIT and several leading computer manufacturers.

**XDMCP**

X Display Manager Control Protocol. XDMCP allows the login server to accept requests from network displays. XDMCP is built into many X terminals.
xDSL

Different types of DSL (page 873) are identified by a prefix—for example, ADSL, HDSL, SDSL, and VDSL.

Xinerama

An extension to XFree86 release 6 version 4.0 (X4.0). Xinerama allows window managers and applications to use two or more physical displays as one large virtual display. Refer to Xinerama-HOWTO.

XML

Extensible Markup Language. A universal format for structured documents and data on the Web. Developed by W3C (page 909), XML is a pared-down version of SGML.

XSM

X Session Manager. This program allows you to create a session that includes certain applications. While the session is running, you can perform a checkpoint (saves the application state) or a shutdown (saves the state and exits from the session). When you log back in, you can load your session so that everything in your session is running just as it was when you logged off.

Z Shell

zsh. A shell (page 900) that incorporates many of the features of the Bourne Again Shell (page 864), Korn Shell (page 884), and TC Shell (page 905), as well as many original features.

Zulu time

See [UTC]
